# THE DENVER ENGINEERING WORKS COMPANY,

DENVER, COLORADO, U. S. A.

## Box Electric Drill.

NO FLEXIBLE SHAFT.

NO SPRINGS.

The entire moving mechanism is so constructed as to require only two bolts to hold it together. There are no keys or setscrews to get loose. All moving parts run in oil-tight case except the motor, and this does not require oil. No ball-bearings or other delicate details of construction.

Examine these cuts carefully; then send for supplement to Bulletin No. 1021.

---

The Denver Engineering Works Company,  
DENVER, COLORADO.

# THE WILFLEY CONCENTRATOR

## NEEDS NO INTRODUCTION.

They are in Use in the Leading Mills of the World.

Eleven Thousand Sold.

Five years ago a prominent mill manager said:  
 "The Wilfley Table saves everything that a gold  
 pan can save and will in time I believe supersede  
 all other concentrating devices."

He was right. The Wilfley Table is replacing  
 all other makes of tables.

Full details in Bulletin S-6. Send for it.

# Our Latest Book on Our Latest Breaker

## Why a Style "K" Gates Rock and Ore Breaker is Best.

- REQUIRES LEAST POWER TO OPERATE. — The "K" style breaker requires less power than any other style of breaker.
- EASY OF FEEDING. — The "K" style breaker is so designed that it can be fed by hand or by a conveyor.
- UNOBSTRUCTED DISCHARGE. — The "K" style breaker has no obstructions in the discharge.
- HIGHEST RANGE OF ADJUSTMENT. — The "K" style breaker can be adjusted to break material of any size.
- EASY SUSPENSION OF SHAFT. — The "K" style breaker is so designed that it can be suspended by a single shaft.
- STRENGTH AND RIGIDITY. — The "K" style breaker is so designed that it is strong and rigid.
- EASY RUNNING. — The "K" style breaker runs easily and smoothly.
- EASY OF MAINTENANCE. — The "K" style breaker is so designed that it is easy to maintain.
- CONVENIENCE IN CHANGING WHEELS. — The "K" style breaker is so designed that it is convenient to change wheels.

Yours for the asking.

Canadian Representatives, Allis-Chalmers-Bullock Ltd., Montreal.

## THE BEST WAY to Treat Slimes is NOT TO MAKE THEM.

**DO YOU KNOW** that hundreds of thousands of tons of ore that defied concentration with the stamp mill have been successfully concentrated after being crushed in the KINKEAD MILL?

**DO YOU KNOW** that tens of thousands of dollars have been taken out of the waste dumps of the Bonanza Mines of the Comstock with this Mill: rock so low in value that it was used to grade the streets with?

**DO YOU KNOW** that thousands of tons of hard quartz from the lower levels of the Comstock have been and are being successfully treated by the Kinkead Mill to-day?

**DOES IT INTEREST YOU TO KNOW** that we are operating six mills and six concentrators with less than 20 Horse Power, and that as far as ease of installation, economy in power and wear, and in even quality of pulp delivered, is concerned, the Kinkead Mill is as far ahead of other mills as the Pullman car is ahead of the stage coach?

**LASTLY, DO YOU REALIZE** that crushing by percussion is wrong in principle, and that crushing by a pressure is the correct way?

**IF YOU WANT TO KNOW MORE** about what the Kinkead Mill can do, write us.

## Henshaw, Bulkley & Co.,

Sole Agents for North and South America, Mexico and Central America,

Cor. Fremont and Mission Streets,

## CARD

Success in concentration depends largely on the machinery employed.

If your mill is equipped with the CARD Concentrator and SPERRY Slimer you are on the road to success.

Floor space required for the CARD, 6x18 feet; for the SPERRY, 11x11 feet.

Late improvements have doubled the capacity of the Card Table.

## TABLE

Write A Postal To-Day

IF YOU WANT TO KNOW  
MORE ABOUT THE

Card Concentrator

AND THE

Sperry Slimer.

## SPERRY

Don't blame the mill man if the values are going down the creek.

Buy him a CARD Concentrator and SPERRY Slimer and save the values. He will appreciate it. So will you. Any mill man can operate them successfully. Hundreds now in use.

The Sperry is a slimer in fact as well as in name.

## SLIMER

# ROLL JAW FINE CRUSHERS

**Crush  
Fine**

FOR

**Stamps, Rolls  
or Mills.**

It costs no more to  
crush fine in  
these machines.

**Crush  
Fine!**

It is cheaper than  
forcing your  
grinding machines  
to do crusher  
work when they  
were designed  
for pulverizing.

**The Only Crusher Able to Crush Large, Hard Ore to  $\frac{1}{4}$  Inch, WITHOUT SCREENING.**  
**FOR FEEDING FINISHING MACHINES, FINE CRUSHING MEANS: ONE-THIRD MORE CAPACITY,**

# Pumps

**JACKSON'S CENTRIFUGAL PUMP**  
— IS THE —  
**WONDER of the AGE**

because there is nothing on the market like it. We are convincing the most skeptical that JACKSON'S HIGH HEAD CENTRIFUGAL PUMP is doing all that we claim for it. That it is taking the place of steam and plunger pumps cannot be denied. That its first cost is less is acknowledged. That the cost for maintenance is reduced to a minimum has been proven. That the efficiency is guaranteed, and that the pumps are designed to raise water 2000 feet or more.

'PHONE, MAIN 328.

## The Vencedora Hot Blast Smelter.

This improved Furnace is adapted for Smelting Copper Ores, Sulphide Ores containing gold and silver, and Concentrates from Vanners or Tables, the Blast being easily adjusted to meet all requirements. Our method of producing this Blast at very high temperature without the use of extra fuel is a new feature and one of our strong claims, effecting great economy in operation.

**These Smelters are Built in Sizes, and with capacity of 8 to 50 tons and upwards in 24 hours.**

The smaller sizes can be packed on mules to locations ordinarily inaccessible, making it an ideal proposition for small mining operations as well as large ones.

They are guaranteed reliable and economical, can be seen working at the Fulton Iron Works, San Francisco. Pamphlets with full information will be mailed upon request.

**THE CONDUCT OF MINING OPERATIONS ON A BUSINESS BASIS INVOLVES THE USE OF THE *BEST* MACHINERY**

These figures are taken from the following sources :

ON THE PISTON DRILL — from an article on page 3136 of the September, 1904, issue of "Compressed Air."

ON THE WATER LEYNER — from a record of eleven months' actual work in the Central Tunnel, at Idaho Springs, Colo., kept by the contractor.

Copies of both can be had free by writing us.

**COMPARISON.**

**THE PISTON DRILL. || THE WATER LEYNER.**

**1. Description of Machines.**

*Specially prepared. Cylinder carefully bored. Special piston of high carbon steel, ground into cylinder. Valve of tool steel. Valve chest carefully bored. "The remaining portion of the machine received very careful attention."*

A stock machine, without any special preparation whatever.

**2. Time Operated.**

Fourteen months. || Eleven months.

**3. Approximate Footage Drilled.**

13104 feet (two shifts) or || 17122 feet (one shift only).

6552 feet (one shift).

**4. Approximate Footage Drilled Per Month.**

468 feet (one shift). || 1556 $\frac{2}{3}$  feet (one shift).

**COMPARISON.**

**THE PISTON DRILL. || THE WATER LEYNER.**

**5. Average Time of Drilling Shift.**

Not stated. || 5 hours, 15 minutes.

**6. Cost of Repairs Per Lineal Foot Drilled.**

\$0.0183. || \$0.0054 (less than  $\frac{1}{2}$ ).

**7. Number Lineal Feet Drilled per Shift per Drill.**

18 feet (364 shifts, deducting || 69.88 feet (245 shifts, actual).  
for 61 Sundays).

**8. Labor Cost per Lineal Foot Drilled.**

(Drill Runner, \$3.50; Helper, \$3.00.)  
\$0.3611 per foot. || \$0.093 per foot.

(Granting equal inbor. However, in the Central Tunnel, only one helper was used for the two drills, thus making the actual cost \$0.0715.)

**WHICH is the Most Economical and Efficient ? ?**

THIRTY-THREE AIR COMPRESSORS with a total capacity of 109,684 cubic feet of free air per minute.

# SHAW'S ECLIPSE AIR-HAMMER ROCK DRILL.

One man with one drill  
does the work of ten men  
with hand drills.

Can be used in any part of  
the mine.

Costs about one-fifth as  
much to install as other  
standard makes and  
requires but one-fifth the  
power to operate.

These drills are being used  
by some of the largest  
mines in the world.

Write us for list of users.

Our Catalogue No. 1 describes WATER WELL  
MACHINES of many sizes, both traction and non-  
traction, for wells 50 to 1000 feet deep, and gives  
full illustrated instructions for operating.  
Catalogue No. 2 describes MINERAL PROSPECT-  
ING MACHINES for exploring for Iron, Lead, Zinc,  
Coal and all minerals. Several sizes, both trac-  
tion and non-traction. Also PLACER GOLD TEST-  
ING MACHINES for assaying Alluvial Deposits,  
Lake and River Beds to bedrock. Can be used on  
boat.  
Also Sectionalized Machines and Boilers for  
easy transportation to difficult places. They make  
6 and 8 inch holes through anything and bring to  
the surface everything found. Full instructions  
for operating.

Catalogue No. 3 describes OIL WELL MACHINERY for wells 1000 feet to 2500 feet deep. Several  
sizes, with full equipment and instructions for operating.  
Our Machines are the sum of all excellence, in use all over the world. Top quality, bottom prices.

## ASSESSMENT NOTICES.

**EUREKA CONSOLIDATED DRIFT MINING Company.**—Location of principal place of business, San Francisco, California; location of works, Placer County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on Friday, the 16th day of December, 1904, an assessment (No. 41) of one-half (½) cent per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, Room 3, No. 214 Pine street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 21st day of January, 1905, will be delinquent, and advertised for sale at public auction; and, unless payment is made before, will be sold on MONDAY, the 13th day of February, 1905, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

CHAS. W. DIXON, Secretary.

Office—Room 3, No. 214 Pine street, San Francisco, California.

**MARINA MARSICANO GOLD MINING COMPANY.**—Location of principal place of business, San Francisco, California; location of works, Sunny Hill, Shasta County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 17th day of December, 1904, an assessment (No. 41) of five (5) cents per share, was levied upon the capital stock of the corporation, payable immediately in United States gold coin to the secretary, at the office of the company, 207 Battery street, Room 15, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 17th day of January, 1905, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on MONDAY, the 6th day of February, 1905, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

CHAS. BOVONE, Secretary.

Office—207 Battery street, Room 15, San Francisco, California.

**MAYDAY GOLD MINING COMPANY.**—Location of principal place of business, San Francisco, California; location of works, Calaveras County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 14th day of December, 1904, an assessment (No. 2) of three (3) cents per share, was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, at Heald's Business College, No. 24 Post street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 24th day of January, 1905, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on TUESDAY, the 7th day of March, 1905, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

EDWARD H. STEARNS, Secretary.

Office of Company—Heald's Business College, No. 24 Post street, San Francisco, California.

Here's a few "Taylor Made" Parts.  
Did you see them at St. Louis?

## "Taylor Made" MANGANESE STEEL Is Best

### FOR HEAVY MINING WORK—

Digging, Conveying,  
Crushing or Sizing Ores  
—in fact, wherever un-  
usual strength and wear-

resistance are prime essentials in the wearing parts of necessary machinery, "Taylor Made" Manganese Steel is unequaled. It is the best for all kinds of rough service.

Look over the biggest Gold Dredges in the field to-day — you'll find the majority of them equipped with "Taylor Made" Manganese Steel bucket-lips and teeth, tumblers, rollers, pins and bushings.

Then there's mine car wheels — of which we make hundreds of patterns, suited to every requirement — and ship carloads almost every week to all parts of the country.

"Taylor Made" Manganese Steel chains and sprockets are the Standard for hard service — they stand up — do the work — and are always ready for more.

Same way with "Taylor Made" Manganese Steel jaw and gyratory crushers, plain and toothed rolls, and cheek plates.

Ditto in the necessary machinery for the coarse screening of heavy and sharp materials — ore, stone or coal.

In a word, "Taylor Made" Manganese Steel castings are ready for business every time, every where, and under every condition — they can "stand and deliver" 365 days in the year if required.

We would like to estimate on any of your heavy castings — and the more difficult the proposition the better we like it.

Maybe we can save you both time and money in 1905.

## TAYLOR IRON & STEEL CO.,

High Bridge, New Jersey, U. S. A.

Beside  
"Manganese Steel"  
we make  
Nickel Steel,  
Carbon Steel  
and  
"Taylor Special."

# CAMERON PUMPS

The  
Cameron  
Vertical  
Plunger  
Pump

To touch again on character—

The character of a CAMERON PUMP has made the CAMERON reputation, and to build up this character and establish this reputation we have had to be exceedingly particular in building our pumps.

To maintain both character and reputation we look to it that every ounce of metal used in a CAMERON PUMP is OF THE BEST. We see to it that every ounce of this "BEST" metal is placed where it will do the most good—to offset wear and tear.

Then again, a CAMERON PUMP is built so as to work along the line of least resistance—few working parts; because, the fewer the working parts and the less power to move them—the heavier we can make them—in order to stand the strain of long continued hard service.

NOWHERE—and CAMERON PUMPS are used EVERYWHERE—has a CAMERON PUMP failed in its duty, or in its ability to work up to full given capacity in situations or under conditions for which it was proportioned and guaranteed.

Truly we have found "Character the grandest thing."

## Improved Methods.

Although engineering features in mining have made many and radical changes in mining methods in the past, innovations continue to be made, and it is impossible to anticipate what new ideas may be introduced in mining within the next few years. The mine which is to-day being operated in an economical and thoroughly up-to-date manner may in a few years have introduced so many changes for the better that the methods now in use, and considered the best practice, will have become obsolete and "behind the times." This is the history of mining in the past, and it will undoubtedly be the experience of the future. An instance is found in the methods lately introduced in the Homestake mine, at Lead, S. D., where very large stopes are now mined with a minimum of timber, and still more recently in the Standard-Mammoth mine, in the Coeur d'Alenes of Idaho. In the latter instance the mine is developed by means of two tunnels having a difference in altitude of 135 feet. The portals of these tunnels are over a mile apart. Between them, and adjacent to the main shaft, a large ore pocket has been excavated with a capacity for holding several hundred

Lexington Hill Gold Mining Co.'s Mill Near Deadwood, S. D. (See Page 4.)

tons of ore. All ore broken in the lower workings is hoisted to this bin and automatically dumped. The chute gates are controlled by compressed air, and the latest devices have been introduced to insure rapid and safe work. The upper tunnel is used for the transport of men and materials only, while the lower tunnel is used for the conveying of ore to the surface. These changes have required months to bring about, and have been accomplished without interfering with the regular output of the property. The result is that mines which were formerly thought to be well managed have introduced new engineering features which have enabled the management to largely increase the output at a lower cost per ton than was possible under the former arrangement, which was considered excellent in its time. It is the constant aim to reduce expense, and it is sought to accomplish this by mechanical means, by taking advantage of situation, or in whatever manner appears possible. The result of this friendly rivalry among mine managers is a constant improvement in methods with lower costs.

## Land Classification.

The classification of lands is one of the most difficult tasks that fall to the lot of those whose duty it becomes to undertake this segregation of mineral from agricultural lands in the western United States. Lands in the West may usually be classified under four general heads: Mineral, agricultural, forest, grazing and worthless lands. In some instances the desert lands, for the time being worthless, may later by irrigation become fertile and valuable as agricultural land. But to determine and set aside the lands "more valuable for mineral" from the other three classes, presumably more valuable for other purposes, is not an easy matter. There may be mineral indications on the surface, and yet the deposits of mineral be too superficial or low grade to yield a profit, while the land upon which it is situated is really valuable for agriculture or horticulture, or some other useful purpose. Again, land apparently valuable for agricultural purposes may conceal beneath its surface a mine worth many millions of dollars to whoever may care to exploit it.

From a humanitarian point of view, it has been asserted by some that any land which will raise a good crop of grain, vegetables or fruit is more valuable for these purposes than for whatever value it may possess as a possible producer of mineral.

Mines are made, and are usually years in the making; so it is clearly evident that to differentiate an undeveloped mineral occurrence from pastoral or agricultural land is often difficult. In view of these facts, it seems well to consider the advisability of setting aside all lands in mining regions and reserving them for mineral entry, regardless of their possible value for other purposes. Mineral lands command the highest price of any of the lands sold by the United States to its citizens, and it seems immaterial in what class they may eventually fall if they are originally purchased as mineral lands and in time prove to be worth more for agriculture, or other uses, than for mineral.

## Mining on the Rand.

During the first eleven months of 1904 the gold mines of the Witwatersrand, South Africa, produced 3,303,905 ounces of fine gold, and the total for the entire year based on the November production was probably not less than 3,640,000 ounces, or about \$75,000,000. This brings the production for a single year to a figure higher than any heretofore reached on the Rand. The highest output prior to the Boer war was reached in 1899, when it was 3,614,985 ounces, or about half a million dollars less than that for 1904. The experience of years on the Rand, the extensive development of the mines to great depth over a wide area, and the thorough knowledge thus obtained of the geology of the banket, its irregularities as to size, and varying gold content, have been of great practical value to the mine managers there. This experience has exploded some of the fallacies of the earlier period of mining on the Rand. The statements had so often been made that the banket could be depended upon to obtain a definite thickness over large areas, and that the values were practically even over these areas, that they became to be looked upon as expressing the actual condition prevailing there. It is now known that the banket is neither uniform as to thickness or value of the ore, and it has been demonstrated that the gold content shows a constantly decreasing average value with great depth. It is also proven that considerable areas of practically non-productive banket occur in some localities. Rich shoots of ore are developed in many places, and these shoots have been shown to possess definite characteristics, and proscribed limitations, not dissimilar from those found in veins.

Many experiments have been made in mining methods and in the treatment of the ores, and these experiments have resulted in the adoption of better and less costly mining. To some extent this also applies to milling. The milling methods, while in a general way similar to those practiced in the United States, do not accomplish as uniformly good results as in America. In the practice of the Rand large capacity per stamp is the one thing aimed at, and with this as high an extraction as possible from the material under treatment, while not reducing the tonnage capacity. The battery screens used are much coarser than is employed in many plants in America, and this, together with the heavy rapid-dropping stamps, gives the large capacity. The tailings, after amalgamation, are cyanided. In most instances the slimes and sands are separated before cyaniding, and the pyrite, which is supposed to carry the greater portion of the gold remaining in the tailings, is treated raw—that is, without previous roasting—and much of it is naturally coarse, due to the large mesh of battery screens employed.

The natural conclusion of one who had never actually worked on these ores of the Rand would be that finer crushing might reduce capacity, thus incidentally increasing milling cost per ton, but it should increase the amount of gold saved by amalgamation, and render possible extraction of gold by cyanidation higher than it is by the present practice. It is possibly true no higher net result may be obtained in this way, but a larger portion of the gold values would undoubtedly be recovered by employing a finer screen, necessitating finer crushing, and the mines would last longer than they will in the feverish haste to gain large capacity. If the ores were crushed through breakers or rolls to finer condition before going to the stamps the capacity would be increased with the present methods and the capacity would probably be as great as now if finer screens were used.

It is not unlikely that in the years to come, when the mines are beginning to show signs of being exhausted, as all mines, even the greatest do, sooner or later, that the tailings now rejected as valueless will be reworked for the values they contain, but which are not at present considered worth the cost. At the present rate of production the amount of ore annually mined and milled is about 8,000,000 tons, and the saving of an additional 10 cents per ton, even at the same profit per ton as now, would mean an additional \$800,000 in gross output. It seems a detail worth looking after, and if it can be done at no greater cost than now it will mean an additional profit of \$1,000,000 annually to the owners of those mines.

## Success in Mine Management.

To achieve success in mining, much depends upon the proper organization of the operative forces. The manager need not of necessity be able to "put in a hole," build a skip, or design a head frame or mill, but he must have that which distinguishes generals and the leaders of all great enterprises—executive ability. If he is not a practical workman himself, and has not had technical training, then, if he would be successful, he must surround himself with men who have these very necessary qualifications, for this is what the successful manager will always do, even though he has had technical training and practical experience, for he knows he cannot undertake the details of management. He is not omnipresent, and therefore cannot be in the mine or reduction works at the same time that his presence may be needed at the electric power station—situated, perhaps, several miles distant. The careful manager will not disdain to place the responsibility of superintendence of the several departments of the industry under his general care in the hands of competent men. He will require good men to look after the mining, mechanical, metallurgical, and probably electrical branches, and in some instances these several divisions are subdivided still further. There are men who have the destinies of a mining enterprise placed in their hands by their friends, who admire him for his success in merchandising and his strict integrity, but whose knowledge of mining amounts to nothing. In his new position there is often a strong temptation to undertake the entire responsibility of designing and ordering equipment, and the direction of all mechanical, engineering and metallurgical features—with what result the history of mining the world over affords abundant unfortunate evidence. A rich mine may possibly pay with any kind of management, but mines of this description are more rare than the over-confident but inexperienced managers.

## The Outlook.

There is at present a noticeable quietude in the camps of organized labor, and the outlook for a year of peace, as far as can be seen on the surface, is promising. In some directions, undoubtedly, legislative action in aid of unionized labor is anticipated, but it is doubtful if the position of those who favor the "closed shop," the "boycott" and "dynamite" can be materially strengthened in that manner. In times of industrial peace, such as now prevails almost universally throughout the country, the benefits derivable from such a state of affairs are clearly apparent and in strong contrast with the deplorable condition existing during the summer of 1904, when workmen and operators alike were arrayed in arms against each other. Both the workman and the employer each have rights which the other must respect, and it is hopeful that the present happy condition will continue for a long period. Under its benign influence investment in new enterprises is prompted, and the success which follows this is an additional incentive to new undertakings and the expansion of existing industries, while the opposite condition results in promptly retarding all contemplated new investment or stopping it entirely, while tying up for a time, perhaps permanently, those enterprises which are in existence, but which have not as yet reached a paying basis. It is an easy matter for the labor agitator to drive capital out of his district, and often it is done without thought or regard of the consequences to those most vitally affected—the workmen themselves.

**A**MONG the advances made in metallurgy the past year have been the successful introduction of the electro-magnetic separator for the treatment of gold ore in which zinc sulphide is a prominent constituent. Several attempts have been made to use petroleum and converter gas in the reduction of iron ores in blast furnaces of the ordinary type, but without the success anticipated by those conducting these experiments. A greater reward, however, attended the efforts to treat fine ore and flue dust from iron furnaces in Pennsylvania, by means of petroleum blast in a furnace of special design, and further experiment in this direction may result in making available a large amount of material heretofore practically lost. These experiments were conducted on new lines and with a highly heated dry blast.

## CONCENTRATES.

RUBBER packing for gaskets and other purposes cuts much more readily if the knife be frequently wet during the progress of the work.

A GOOD speed for a driving bolt is 3000 to 4000 feet per minute. In leather belts the direction of driving should be with and not against the laps in the belt.

THE strike of a vein is its direction horizontally. The trend of an ore shoot is its dip along the strike of the plane of the vein. The dip of the vein is at right angles to the strike.

WHEN a ton of quartz or other rock contains \$20 in gold, the gold represents one part in 29,166 parts, and if the value be but \$2 per ton, the gold represents but one part in 291,666 parts.

SOME mill men tie the wedges around the shank of a shoe with a string; others have the wedges tacked to a strip of cloth in order that they may be promptly adjusted when required.

FLUORSPAR is sometimes used in the manufacture of Portland cement. It is claimed to facilitate the semi-fusion of the finely ground material, thus forming what is known as "clinker."

IT is no more economical to run an engine with an underload than it is to run one with an overload. It is always wise to provide ample power, but the installation can be easily overdone.

CEMENT acts as a protector to iron and steel used in its reinforcement. Steel bars so used have been found with practically no sign of rust after having been embedded in concrete for over twenty years.

A CROSSHEAD for shaft sinking may be made of angle iron, and it would probably be as serviceable if not better than one made of wood. The plates could be riveted by the blacksmith. If the material is at hand it would probably be cheaper than wood.

NEARLY all copper ore deposits occurring at or near contact of limestone with other rocks contain garnet in abundance. The idea that the appearance of garnet is a sign of a poor mine is a fallacy, for some of the largest and most profitable copper mines are accompanied by abundance of garnet.

THE appearance of scattered but rich small pockets of ore in a large rock mass is not a safe indication that these deposits will be found to increase in size and number until a large, solid body of ore is formed in depth. Numerous stringers appearing at the surface sometimes unite to form a solid vein below.

THE frequent earthquakes being of late recorded in California are supposed to be due to the interior cooling of the earth, and the consequent shrinkage results in compensating movements of the outer crust of the earth—the rocks which may be seen in the hills and mountains in the workings of mines. All regions are likely to be similarly affected. Seismic disturbances occur in all parts of the world and are practically of daily occurrence.

A FATHOM is 6 English feet. Mine workings are not usually measured in fathoms except in Cornwall and a few places in the United States, where the custom has been introduced from England. A vara is a Spanish yard—32.8748 inches. It is often used to denote the extent of mine workings, and also of the superficial measurement of mining ground. In California, the legalized vara is 33.372 inches, and the legua (league) is 5000 varas, or 2.6335 United States miles.

THERE is a great difference in the manner in which different men fire a boiler. A careful man who has been properly taught, or who has learned from experience, will use much less fuel than another who either does not know or is careless, and consequently extravagant. Coal should be fired frequently and in even thin layers. Too heavy a charge will cause a prompt and decided lowering of temperature with a great increase of temperature as soon as the coal gets to burning brightly.

TO lay  $\frac{1}{2}$  mile of track (5280 feet of rails), using twelve-pound rails, will require about nineteen tons of rails beside fish plates, bolts, nuts, spikes, etc. If sixteen-pound rail is used, twenty-five tons of rail will be required. It is not necessary to use fish plates underground. Thousands of feet of track are in use in mines where no fish plates are in use. If the ties are heavy enough to use good-sized spikes, no fish plates are required. Where heavier tramping is done on the surface it is advisable to use fish plates on permanent tracks.

FUSE is known as single, double and triple tape, cement fuse, gutta percha fuse, etc. Each fuse is made in much the same manner—a thin and continuous string of powder surrounded by a wrapping of hemp or other material and covered on the outside by a single, double

or triple thickness of tarred tape tightly wound. In the case of cement fuse a composition impervious to water is substituted for tape, and gutta percha is only another variety of covering. In wet places or under water the best varieties of fuse should be employed.

THE duty of the miner's inch (1.5 cubic feet per minute) of water in moving gravel is variable, depending on the head and volume of the water used, and to a great extent upon the character of the gravel, and the grade, which may facilitate or retard the clearance of the gravel from the working place. The miner's inch varied so greatly in quantity, by reason of the variable head employed in measurement, that the California and Montana Legislatures fixed the amount at 1.5 cubic feet. Under a head of  $6\frac{1}{2}$  inches—that is,  $6\frac{1}{2}$  inches from the surface to the center of the orifice—1.53 cubic foot of water will flow in one minute through an aperture 1 inch square.

LOCOMOTIVE BOILERS are frequently seen about small mines, and sometimes at large ones. A boiler of this type is convenient, particularly in the smaller sizes, and is often mounted on wheels in order that it may be moved readily from place to place. For prospecting purposes, they are much in favor. The locomotive or firebox boiler is as extravagant of fuel as it is convenient, but its usefulness may be greatly increased if the feed water be heated and a damper be placed in the stack, in order that the combustion of the fuel may be controlled somewhat. This kind of boiler can be used to run hoists, pumps, quartz mills, saw mills and other machinery not requiring too great power.

THE largest number of stamps in operation under one roof is 300, in one of the mills of the Alaska-Treadwell Gold Mining Co., Douglas Island, Alaska. This company has another mill of 240 stamps. The gold output of Venezuela is difficult to arrive at, owing to high export duty, which acts as a sort of premium to smuggle gold out of the country. Official reports credit that country with a production of 41,200 ounces to as high as 49,000 ounces within the past ten years, with a probable average of about 43,000 fine ounces annually—or about \$8,600,000 during the past ten years. The annual output of Venezuela was considerably higher about twenty years ago, when the great Lode El Callao was being vigorously worked.

In pumping against a closed valve with a multi-stage turbine pump, or any other kind, the gauge should indicate a pressure equal to the total head necessary to raise the desired quantity of water. This depends upon the length of the pipe,  $L$ , its diameter,  $d$ , and coefficient of friction. The total head,  $H$ , is equal to the sum of the vertical lift,  $h$ , the friction head,  $h_1$ , and the velocity head,  $h_2$ . The velocity head is equal to  $\frac{v^2}{2g}$  where  $v$  is equal to the number of cubic feet discharged divided by the cross-sectional area; the friction head is  $f_1 \frac{L}{2g}$  where  $f_1$  is the frictional head for 100 feet of pipe of given diameter and for given velocity, obtained experimentally and given in hydraulic tables. The formula is  $H = h + f_1 \frac{L}{2g} + \frac{v^2}{2g}$ .

THE efflorescence appearing on the face of concrete walls is due to the seepage through the wall of moisture, carrying lime or other minerals in solution, which are deposited on the wall upon the evaporation of the water. This is usually observable along approximately horizontal lines, which represent the several stages of the successive days' work. It has been suggested that this may be prevented by giving the upper surface of each separate layer placed in the wall, a backward slope toward the rear of the wall and sprinkling a layer of neat cement on this upper, but unfinished surface. This forms a layer almost impervious to water and when moisture percolates downward through the concrete, on reaching these several impervious inclined planes, the water will be trained backward to the rear of the wall instead of to its face, and, in time, the soluble minerals will be completely dissolved and removed from the concrete.

THE thawing of nitro powder is always attended with danger, and too much care cannot be taken in this matter. When warmed, nitroglycerine oozes from the absorbent, and if it collects in a drop this drop is dangerous, for, falling on any heated object, will explode in the great majority of instances, and this explosion is likely to have the effect of exploding the main mass. Dynamite may be safely thawed in several ways. One, said to have been employed on the Croton Aqueduct work, was that of placing a cubical box 30 inches square within a box 48 inches square, the space between the boxes being filled with green stable manure packed hard. The boxes were set in a hole in the ground and filled round with 18 inches of loosely packed manure, the floor of the thawer being filled to a depth of 10 inches with tightly packed manure. The space above will hold conveniently fifty pounds of nitro powder. The cover had a stovepipe ventilator 3 feet high, and was provided with a sliding cover, to make access to the interior convenient. The sticks of dynamite were laid in loosely, the lid closed and green manure piled over it to the depth of a foot. The powder would thaw in from three to eight hours, depending on the degree of the tem-

perature outside. This method of thawing frozen nitro powder is safe; no rapid changes of temperature occur, and it is inexpensive.

GEOLOGICAL STRUCTURE has often a decided influence on the topography of a region. A fault may produce a cliff extending sometimes many miles. The contact between two formations often results in the erosion of a canyon along this line. Hard rock strata often produce ridges, and bosses of hard rock, rounded or rugged, isolated hills. Synclinal folds usually produce valleys, though not always, as the compression of rocks in a synclinal trough may render them so hard as to make them better able to resist erosion. The axis of an anticlinal is often indicated by a valley, as the rocks are fractured and thus rendered more easy of removal by erosion. The course of a vein is as often indicated by a line of depression as by a bold outcrop. The reason for this is due to the fact that the walls of a vein are often impregnated with the sulphide of iron which is disseminated in grains throughout the rock, often to a considerable distance on either side of the fissure. This renders the country rock much more easily susceptible to decay and oxidation of the sulphides, which facilitates erosion. Many other instances might be mentioned to show that geological structure has a very important influence on surface topography, like flows of lava over the country, which usually result in producing long, flat-topped ridges or table lands.

THE probable value of the ore which may be found at a greater depth than that exposed in a copper mine would be a difficult matter to satisfactorily determine. The engineer may be able to form a very fair judgment from what he can see of the probable continuity of the ore downward, but its value can only be guessed at. In many important copper mines the gossan is practically destitute; in the zone next below the iron capping the ore is abnormally rich, and in depth (in the normal sulphide zone) the ore is a low-grade mixture of copper and iron sulphide and gangue, and often also pyrrhotite and other minerals. The climatic conditions and topography of the country have much to do with the oxidation of the sulphide ores and the position of the various alteration products as related to the surface. Thus in a country where oxidation proceeds more rapidly than erosion a heavy iron gossan is not infrequently seen on the surface, while in a desert region, while oxidation may be more rapid than in a comparatively moist region, the rate of erosion is even more rapid and the iron capping is thinner or it is accompanied by the oxides and carbonates of copper, under which are found the enriched sulphides of which chalcocite (copper glance) and bornite (peacock copper ore) are examples. Beneath the zone in which these ores occur is the normal sulphide zone, but this may be deep seated, as at Clifton, Ariz. In many regions the normal zone is found within 200 feet of the surface. Although the greater portion of the zone of mineralization is above 1000 feet from the surface, there are places where the zone of enrichment extends to greater depth and many hundred feet below the level of the ground water of the district. In some mines there is practically no zone of oxidation or enrichment, which is probably due to climatic and topographical conditions.

CYANIDE SOLUTIONS are decomposed to a greater or less extent by many mineral substances commonly occurring in ores. The solution affects almost all of these substances more or less, and is itself affected by them, but the success of the process is based upon the fact that gold and silver in minute particles are more readily affected than are the other minerals usually occurring with them. Pyrite affects cyanide to a slight degree. Metallic particles of iron and steel which result from the crushing of the ores are disseminated throughout the mass of ore treated and dissolve slowly in cyanide solutions. Metallic copper is also slightly soluble in the solution. Copper sulphides usually accompany gold and silver ores, being present from a trace up to rich ore of copper. All the copper sulphides are soluble in cyanide solutions, but some more so than others. The presence of other mineral substances often facilitates the dissolution of copper ores in the cyanide solution, as many interesting reactions take place. The best way to determine the amount of cyanide consumed by the presence of particular substances is by test. Chemical analysis only cannot be relied upon to give the desired information. Mispickel (arsenical iron sulphide) is acted upon by cyanide, but very slowly. Some gold ores containing abundant arsenical sulphide have been successfully treated by the bromo-cyanide process. Stibnite (antimony sulphide) decomposes cyanide readily, and is one of the most objectionable substances with which cyanide operators have to deal. Owing to the reactions which take place in the solutions, gold and silver are sometimes rendered practically almost insoluble in cyanide solutions. Mercury, which is usually present in tailings, is soluble in cyanide. Some operators claim this metal aids in the process, others say it is a detriment. This must be considered as representing the individual experience of these several operators, and neither statement accepted as positive in all cases. Zinc sulphide is not considered as very disadvantageous if the mineral is fresh from the mine and has not had long exposure to oxidizing influences. Galena (lead sulphide) is similar in its action to zinc sulphide, and is not particularly objectionable to the cyanide operator. In each of the instances here mentioned special tests must be made to determine the amount of decomposition of cyanide by these several minerals.

## Important Mines Near Deadwood, S. D.\*

Written for the MINING AND SCIENTIFIC PRESS.

There are no mines within the corporate limits of the city of Deadwood, although a good portion of the town is built on worked-out placer mines which paid handsomely during the years from 1876 to 1878. Though surrounded by large and rich mines and ore deposits, none of these occur, so far as known, within half a mile of the town, the nearest being the Montezuma and Whizzers, operated for the iron pyrite which occurs abundantly in the great lode on which these claims are located. These mines have been extensively drawn upon to furnish sulphide material for the pyritic smelter of the Golden Reward Co., in which are treated the siliceous ores obtained from mines near Terry Peak. These flux mines are owned by J. T. Gillmore & Co. of Deadwood. The ore deposits occur associated with a heavy reef of quartzite, which can be traced for many miles over the hills to the southeastward from Deadwood creek, but which passes beneath the lower member of the overlying Cambrian rocks half a mile away to the northwestward. This zone is 40 to 100 feet in width and carries chiefly pyrites, with a little chalcopyrite in the quartz gangue. The inclosing walls are mica schist, hornblende schist, etc.

Although there are represented within the city limits of Deadwood all of the several geological horizons at which ores occur in the Cambrian, Silurian and Carboniferous formations, within the Black Hills, there are no ore deposits of value known to exist in these rocks in this town. The Cambrian exposures are complete from the basal quartzite to the upper quartzite, distinguished by the abundant appearance of the fossil *Scolithus*. The Cambrian formation has a thickness here of about 450 feet, but thins out southward until in the southern Black Hills, near the south fork of Castle creek, it is not over 50 feet in thickness.

Overlying these Cambrian quartzites, shales and glauconitic sandstones are the calcareous shales and limestones of the Silurian and Carboniferous. The presence of the Devonian has been questioned, but the writer is of the opinion that fossils found on the eminence just east of Deadwood, locally known as White Rocks, identify the Devonian horizon.

It is in these sedimentary beds that the gold, silver and lead-bearing deposits which have attracted so much attention of late years occur, and which are generally referred to as the "siliceous ores," to distinguish them from the ore found in the Archaean schists upon which these sedimentaries rest.

All about Deadwood, particularly to the east, north and west, eruptive rocks of several types have been intruded into the Archaean and overlying sedimentaries, but these occurrences, known to be favorable to mineralization and the formation of valuable ore bodies, are not always accompanied by deposits of ore of commercial value. To the eastward of Deadwood, however, in Spruce gulch and on the divide between Spruce gulch and Two Bit creek, there are extensive and valuable ore deposits occurring at several horizons in the Cambrian and later formations. In the basal member, the Quartzite, occurs lead-silver ore; about 200 feet higher, lead carbonate ore is found in glauconitic red sandstone, and gold also is found in loosely coherent coarse sand rock, and in a dense, hard siliceous limonite. Ore deposits are known in and near the upper quartzite, and a chimney of gold-bearing iron ore is found in the carboniferous limestone on Lexington hill. Beside these several ore-bearing horizons, there are numerous zones in which occur "stocks" of iron oxide (presumably oxidized pyrite) in the porphyry intrusions. Ore deposits of this class are numerous on the divide between Spruce gulch and Two Bit, and similar occurrences are known near Galena and in the Bald mountain district.

The Spruce gulch section is rugged, and, owing to the numerous faults and porphyry intrusions, the geological structure is somewhat complicated, and an understanding of it is rendered more difficult by the large amount of talus which often obscures the rock formations. In this region one of the principal properties is that of the Lexington Hill Gold Mining Co. Originally this company owned the single claim known as the Old Lexington, at the summit of Lexington hill, on the divide between Spruce and Two Bit gulches, a mile and a half east of Deadwood. The Lexington Hill Co. consolidated the properties of five separate corporations, and their holdings are now among the most extensive controlled by a single company in Lawrence county. The area of mining ground thus consolidated is 350 acres. The greater portion of the ore is found in the Cambrian shales and quartzites. Thus far, five separate ore-bearing horizons are known. The formation is much disturbed in places and the ore beds are found lying at all angles, from nearly horizontal, as in the Champion mine, to about 60° pitch, as in the Annie. In the early days of the district the Champion was the most extensively worked of any of these mines, and many thousands of tons of good ore were milled in an ordinary stamp mill in which simple amalgamation was the only practice. This was done in the years about 1879 to 1882. There were

frequent stoppages, when neither mine nor mill were operated for months at a time. This is not surprising, for the mill men were at their "wits' end" how to save the gold. Cyaniding was unknown, and chlorination, though commonly practiced elsewhere, had never been introduced in the Hills. The old mines are a labyrinth of shafts, winzes, levels and irregular excavations from which the ore was taken. Much of this ore was high grade, running from \$15 to \$200 per ton. The average, however, was much below this. Ore from \$5 to \$20 per ton is abundant. The development work was done in a random, haphazard fashion, in search of high-grade ore, but the present company has introduced a system of development which will greatly facilitate mining and cheapen its cost.

The accompanying illustration is that of the Lexington Hill mill in Spruce gulch, about a mile from Deadwood by road. A tunnel has been driven into the hill back of the mill, as shown in the illustration on the front page. This tunnel is started below the lowest Cambrian stratum, and will be run 3000 feet to a point under the crest of Lexington hill. This cheapens mining, as all ore broken above the tunnel level can be handled by gravity.

The milling process is by amalgamation, concentration and cyaniding tailings. The average value of the ore is stated to be \$6 per ton.

## The Bassick Mine, Querida, Colo.

One of the most interesting mines in Colorado is the Bassick, near the town of Querida, in Custer county. The remarkable ore shoots of this property occur in an agglomerate of andesite within a rudely elliptical fissure, or vent, which at the surface was 20 to 30 feet in width and 100 feet long. It extends downward almost vertically, but winding somewhat. It is a typical pipe or chimney. It is practically without walls, and there is no line of demarkation between ore and barren country rock, the values disappearing by gradual transition from rich silver-gold ore to that which is commercially worthless.

Within the zone of fracture which some presume to be a volcanic vent, though this is unlikely, the fragments of the breccia or agglomerate range from that of pebbles to boulders 2 to 3 feet in diameter. These

Ore Shoots Bassick Mine, Custer County, Colo.

fragments are rounded, or subangular, few having sharp edges. Its condition varies from soft, earthy and crumbling, to dense, hard and flinty. At times boulders of the secondary silica are found embedded in masses of kaolin. The remarkable fissure has maintained its structural characteristics to a depth of nearly 2000 feet from the surface outcrop.

The richest ore occurs in the central portion of the deposit, the values generally lessening as distance from the center of the mass increases. It is a curious fact, also, that the average size of the fragments of rock (andesite), at the center are larger than those in the zone surrounding it.

The mineral composition of this unusual type of ore deposit is as peculiar as its structure is uncommon. There is in this deposit neither calcite, heavy spar, nor any other of the spar minerals that are generally found associated with ore deposits. The minerals occurring in the deposit are chiefly the sulphides of zinc, and lead, antimony and copper, with the secondary minerals resulting from their alteration in the upper or oxidized portion of the deposit. These

minerals are the carbonates and silicates of the base sulphides, together with tetrahedrite (gray copper), silica, gold and silver.

These minerals were found arranged in concentric shells or layers, around the boulders of the deposit. The shells are of about the same thickness and follow each other in the same order on all of the boulders, there being generally three and sometimes four separate layers observable. From within outward, they occur as follows:

First. A thin layer of the sulphides of antimony, zinc and lead, black in color, with metallic lustre and crystalline structure. This layer varied from a thin line to  $\frac{1}{2}$  inch in thickness, and carried from 1 to 3 ounces gold and 60 ounces silver per ton.

Second. A layer of lighter color, in which there was a larger amount of lead, silver and gold than in the layer underneath it, and running sometimes 100 ounces gold and 150 to 200 ounces silver per ton.

Third. A layer of crystallized zinc blend, containing also some iron and copper. It was from  $\frac{1}{2}$  inch to 2 inches thick, carrying 15 to 50 ounces gold and 60 to 120 ounces silver per ton. Owing to its relative abundance, this layer constituted the most valuable source of revenue in the mine.

Fourth. When it was present, this fourth shell consisted chiefly of chalcopyrite. In thickness it varied from a few grains scattered on the outer surface of the blende to  $\frac{1}{10}$  inch. It contained 50 to 100 ounces gold and silver.

Fifth.—Outside of this there occasionally appeared a thin sprinkling of pyrite. Strangely, this mineral, usually so abundant in ore deposits, occurs sparingly in the Bassick mine. Among the larger boulders the filling was generally kaolin. The mineral comprising the first, or inner shell, of the larger masses was always found present, as it covered the smaller pebbles and cobbles, whether the other shells occurred or not. It is a combination of antimonial lead. The zincblende layer, which is so pronounced in the heart of the ore body, is entirely absent in the outer portions of the deposit.

The gray copper was always found associated with quartz and outside of the shells in the interstitial spaces between the boulders. Quartz is also found in the open spaces between the boulders and never as a portion of the shells.

A curious fact in connection with this mine is the finding of fragments of charcoal to a depth as great as 765 feet. The charcoal often was found to have fine crystals of pyrite scattered throughout its pores.

Charcoal is also found in some portions of the Comstock Lode hanging wall, at Virginia City, Nev., and in the mines of Bodie, Cal.

These several occurrences of charcoal several hundred feet from the surface have been thought to be due to the fact that there have been several periods of eruption of the andesites, and that the interval between them was sufficiently long for trees to either grow on the surface of the flow or tufa deposit, or to be carried there by some means, and that the tree was enveloped in the next succeeding flow or deposit, to be, in time, converted to charcoal. This theory, if accepted, indicates the probability that the Bassick ore deposits have occurred at the joining plane of two separate deposits of fragmental andesite, or that the wood from which the charcoal was formed was involved in the andesite tuff or breccia in some manner, to be later turned to charcoal.

The origin, or genesis, of the Bassick ore deposits has been the subject of much speculation and a great deal has been written on the subject. Among the theories advanced are that of an "active volcano," where the rocks were ejected, falling back into the vent only to be again ejected, thus, in time, becoming rounded, like washed boulders.

This explanation will not account for the several peculiar structural phenomena observed. Had the rocks been ejected as suggested, only to fall back to be again ejected, until they finally came to a state of rest by reason of decrease of volcanic force from below, they would have lain in immediate contact with each other. This is not the case, however, as the boulders do not touch, and no known force could have kept them suspended in air, as it were, until the sulphide mineral shells had been deposited to fill the spaces between.

The more reasonable supposition is that the deposition of mineral is due to thermal springs rising from depth and carrying the minerals in solution found in the deposit. This mineralization took place along a line of fracture, somewhat illy defined, it is true, but probably having a direction common with the major axis of the ore body. The rings or shells of mineral deposit seem to be due to the concentric decomposition of the andesitic boulders themselves, a phenomenon not at all uncommon in the weathering or alteration of many massive rocks. The concentric shells were replaced by the mineral solutions, in much the same manner as metasomatic replacement occurs, in bands within fractured zones, elsewhere. As to the relative age of the several shells, that seems more difficult of solution. The natural inference is that the outermost shells, being the first to suffer alteration, were also the first to be replaced by the minerals of the sulphides coming from below.

It seems, without doubt, that the ore deposits of the Bassick mine are due to the last active evidence of volcanic action in the form of a fumarole or hot

\*See illustration front page.

spring, possibly accompanied by hot water and the escape of steam at the surface.

The peculiar mineralization of the deposit may be due in part to secondary causes. There are other deposits in that portion of Colorado not wholly dissimilar, and these occurrences throw much light upon the origin of ore deposits in zones of fracture and brecciation.

## The Genesis of the Copper Deposits of Clifton-Morenci, Arizona.

NUMBER II.

Written by WALDEMAR LINDGREN.

The Longfellow limestone, though somewhat irregularly altered, is, next to the contact, generally transformed into a coarsely granular rock of garnet, epidote, diopside, magnetite, pyrite, zincblende and chalcocopyrite, and there is a most decided change of composition, chiefly consisting in additions of silica and iron. Other parts are less altered, but contain much magnetite, together with the sulphides mentioned, disseminated through a medium-grained crystalline mass of the carbonates of lime and magnesia. The development of magnetite, metasomatically, is a most pronounced feature of the process. Looking at the formation as a whole, sulphur, iron, copper and zinc have certainly been added, and probably also silica and magnesia. Large masses of magnetite,

The metasomatic development of magnetite in pure limestones which has recently been questioned by Prof. Klockmann may be observed in almost countless localities at Morenci and Metcalf, both in the field and under the microscope. It is known that iron was not contained to this extent in the original rock, but to demonstrate its actual derivation in each case is, of course, difficult. The question becomes clear only when we compare the contact zone as a whole with the original unaltered rock.

It seems very strange than any one can doubt the possibility of such conditions and overlook what must happen when a magma in aqueous fusion is suddenly brought up to higher levels and strongly ionized water-gas above the critical temperature is largely released from its bonds. It must of necessity contain dissolved substances. Even at comparatively low temperature water is one of the most powerful solvents known, and its action, when a perfect gas, is probably far in excess of that at 100° or 200° C. It is well known that some rapidly congealed rocks, like the "pitch stone" from Saxony, contains up to 8% of water, which indicates an amount of water-gas which per cubic meter of magma would at + 4° C. correspond to from 250 to 300 liters. All magmas may, of course, not have contained this amount. The water-gas seems to have penetrated the limestones like a sponge, inducing extreme molecular mobility. Even should we deny any additions of substance, a most remarkable transferring of substance has certainly taken place in the rock, as shown, for in-

pyritic veins are of low—generally unpayable—tenor; they consist of prevailingly granular or massive, very rarely crustified, minerals with a little quartz-gangue, and are believed to have been formed by pyritic replacement along well-defined fissure planes. In the porphyry these veins are surrounded by very wide zones, in which the rock is greatly altered by the introduction of sericite and pyrite, and this applies to Metcalf as well as to Morenci. At the latter place, almost the whole of Copper mountain, containing the most important lodes, is thus altered. The process, which in the complete report is elucidated by many analyses, produces bleached rocks of varying hardness, in which all of the feldspar has been replaced by sericite and some pyrite. The biotite and hornblende are transformed into chlorite and serpentine, while the silica of the rock remains almost constant. All of the lime and soda are eliminated, while potash is greatly increased; no carbonates form during this process.

RELATION OF CONTACT AND HYDROTHERMAL METAMORPHISM.—The alteration of limestone along fissure-veins to tremolite (or diopside) with magnetite and sulphide is, as far as I know, a novel one. Ordinarily, limestone alters next to fissure-veins to dolomite or quartz or jasperoids. The addition of silica and iron and the mineralogical result of the hydrothermal process at Morenci undoubtedly connects it in some way with contact metamorphism. It is also probable that an alteration of this kind took place at high temperature comparatively soon after the

Arizona Copper Co.'s Works, Clifton, Ariz.

locally used as a flux, have been mined at this horizon.

The Morenci shales have suffered a change to dense, greenish hornfels with a development of amphibole and, in places, also muscovite. Pyrite and magnetite are also present, but on the whole the change in composition is probably slight.

The Modoc limestone, containing about 96% of carbonate of lime, has proved extremely susceptible, and over large areas at Morenci, as well as at Metcalf, is converted to a massive sheet of lime-iron garnet; magnetite is usually present; epidote and oxidized copper ores are also of frequent occurrence. This transformation, involving large additions of silica and ferric iron, is very noteworthy, as the evidence is entirely uncontrovertible.

The contacts of the sedimentary series and the porphyry are sharp and show no evidence of assimilation. All of the contact metamorphic rocks, when unaffected by oxidation, are very compact and hard, atmospheric waters finding great difficulty in attacking them. Considering that great amounts of carbon dioxide have been expelled during the metamorphism, it is clear that a great shrinkage of volume should have taken place if no additions of material had been received. Such a reduction of volume has evidently not taken place, and I believe that any loss has been fully balanced by gains from material contained in magmatic solutions.

Study of the Morenci contact zone proves conclusively that important accessions of substance have been received. The rocks inside the altered zone contain an enormous quantity of sulphur, iron, copper and zinc. Iron is contained in the unaltered rocks to some extent, but nothing like the quantities in the contact zone; sulphur, copper and zinc in noticeable amounts are absent from the unaltered rocks. Were they present, to the extent of a small fraction of the percentage contained in the contact-zone, direct observation and surface oxidation would expose their presence. The minerals in which these substances are contained were certainly formed contemporaneously with the ordinary contact minerals of the district, like garnet, diopside and epidote.

stance, by large crystals of garnet developing in limestones of uniform composition containing far less silica than the amounts required by the newly formed mineral.

A misapprehension of the character of contact deposits seems to exist in many quarters, in considering the presence of minerals containing boron, fluorine, etc., as necessary to prove the contact-metamorphic character of these deposits. The character of magmatic waters evidently varies greatly in different magmas. Some may carry large quantities of the substances mentioned, as shown by the presence of tourmaline, cassiterite and other minerals in the contact-metamorphic rocks, while others may be almost wholly deficient in them, and, instead, carry sulphur, copper, iron and other metals. In the Clifton group of deposits, I would be inclined to consider molybdenum a characteristic constituent, taking the place of tungsten in the tin deposits. Any attempt to reduce the wonderful variety in the contact-metamorphic deposits to a single pattern is doomed to failure.

As the result of wide observations, we would state, as far as we know at present, ore deposits may occur several hundred or even 2000 feet away from the contact. In fact, disseminated sulphides and magnetite occur at Morenci up to 2000 feet from the main contact.

A tabular form of deposits often noted is usually due to the strongly marked difference in susceptibility of the various beds. Wherever the deposits have been enriched by oxidation, the form may be more or less dependent upon these changes.

W. H. Weed has noted the tabular shape in contact deposits at Cananea, Mex., and makes the form a basis of classification. I do not believe, however, that distance from contact (within limits given above) and shape are at all essential, and can find no mineralogical difference between deposits varying in these respects.

HYDROTHERMAL METAMORPHISM.—Both the porphyry and the contact zone are traversed by fissure-veins, which carry pyrite with a small quantity of chalcocopyrite, zinc blende and molybdenite, whenever oxidation has not changed these minerals. These

solidification of the porphyry.

The vein alteration produces dull, earthy rocks from the limestone, while contact metamorphism results in hard, compact and granular rocks. On the other hand, there is undoubtedly a certain relation between the two processes, for amphibole (and pyroxene) occurs in the true contact-metamorphic rocks, and the intergrowth of magnetite and pyrite is characteristic of both. I should, therefore, conclude that after the completion of the contact metamorphism, properly speaking, and after the consolidation of the porphyry, an extensive fissure took place and solutions derived from the cooling porphyry, probably ascending and laterally extending from this rock, flowed through these fissures. Everything indicates that these solutions were closely related to those which emanated from the magma at the moment of intrusion and, in fact, similar in general composition.

PROCESSES DUE TO OXIDATION AND HYDRATION IN THE ALTERED ZONE.—Under influence of surface waters, but protected from direct oxidation, chlorite and serpentine form from the tremolite and diopside of the contact zones, while garnet is little altered. Under direct oxidizing action, garnet changes to limonite and quartz, while lime is probably carried away as carbonate. Tremolite and related minerals are similarly affected. Magnetite oxidizes to hematite and limonite, many large bodies of which are mined for fluxing purposes.

The veins are marked by siliceous outcrops, either entirely barren or containing small amounts of oxidized copper ores. No basic ferric sulphates have been seen either in the mines or on the surface. The waters percolating downwards must soon have lost their oxygen and, for the alteration at greater depths, ferrous sulphate and diluted sulphuric acid are probably the only reagents of importance resulting from the pyrite. It is clear that the upper part of the veins have not been formed by simple oxidation of pyrite and accumulation of limonite.

Direct oxidation of chalcocopyrite yields cupric and ferrous sulphates, while the zinc blende produces zinc sulphate; both of these processes are in evidence wherever disseminated sulphides in the meta-

morphic rocks are exposed to oxidation. The general order of attack of oxygen is usually stated as follows: Arsenopyrite (most easily attacked), pyrite, chalcopyrite, blende, galena and, finally, chalcocite (most difficultly attacked). This rule is probably true only for one set of conditions as to mass, aggregate and character of solutions. Very marked exceptions from it occur at Morenci.

**SULPHATE WATERS.**—Descending waters from a lode of decomposing pyrite, chalcopyrite and zinc blende should contain chiefly ferrous, cupric and zinc sulphates, together with free sulphuric acid. The first two salts are easily soluble, but far more so is the zinc sulphate.

Cuprous sulphate is stable only under certain conditions and is not believed to be an important reagent, though it may form during subsidiary or intermediate reactions. Its presence in any mine waters has not been satisfactorily proved.

In this district, some moisture percolates the upper workings, as shown by efflorescences and stalactites of sulphates, but the mines are practically dry. In the porous porphyry, the moisture spreads easily, while the hard metamorphic rocks offer considerable resistance.

**PROCESSES IN FISSURE VEINS.**—Below the region of oxidizing influences, the veins consist of pyrite, chalcopyrite and zinc blende, while the upper few hundred feet contain chalcocite and oxidized copper ores. The most important action of the descending sulphate solutions has been a development of chalcocite by the action of cupric sulphate on primary pyrite ore; this process began at the time the veins were first touched by oxidizing waters, and continues to some extent to the present time.

**OXIDATION OF CHALCOCITE.**—After a large part of chalcocite in the lode had been formed, there came a time when erosion and degradation, working faster than oxidation, began to expose the upper part of the chalcocite zone to active and direct attack by oxygen. Practically all of the veins are in this stage. The present zones of active oxidation are therefore due, not to direct oxidation of the primary lode, but to the destruction of the upper horizon of the chalcocite zone. As reagents, there are here ferrous sulphate, sulphuric acid, cupric sulphate and free oxygen. Any ferric sulphate present would soon be reduced to ferrous salt by the abundant pyrite. Chalcocite changes to cuprite and cupric sulphate, sometimes with an intermediate stage of covellite. Cuprite, partly reduced to metallic copper, is abundantly present in the upper limit of the chalcocite zone.

By some process not quite elucidated, chalcocite may, in places, change directly into native copper. The zone of cuprite and metallic copper has rarely great vertical extension, for the reason that both minerals are rapidly converted into cupric sulphate, brochantite, malachite, azurite and chrysocolla; but these products are soon dissolved by free sulphuric acid from pyrite, some of which tenaciously remains until the last, and descend as soluble sulphates to enrich the upper part of the chalcocite zone.

**OXIDIZING PROCESSES IN LIMESTONE.**—The processes which have resulted in the oxidized deposits now forming irregular or tabular masses in limestone or shale, and not connected with fissures, are materially different from those occurring in the lodes. In most cases the original material consisted of disseminated lean pyritic ores, containing pyrite, chalcopyrite, zinc blende and magnetite, locally more or less concentrated in irregular masses, or following certain strata or dike contacts. Free oxygen and sulphuric acid, ferrous and cupric sulphates, with an abundance of calcium carbonate, formed the reagents. Though oxygen and carbon dioxide may in part have produced limonite and malachite directly from pyrite and chalcopyrite, the most important reactions doubtless were those between calcium carbonate and sulphate solutions, partly derived from nearer the surface.

In the first case malachite, in the second azurite forms, together with gypsum. The latter mineral, though largely carried away in solutions, is not uncommon in these deposits at Morenci. Ferric hydrate will be produced from ferrous sulphate and calcium carbonate. Thus, in general, is explained the constant occurrence in these deposits of malachite, azurite and limonite. Crusts of replacing malachite and azurite frequently surround residual, rounded masses of limestone. The gangue of garnet and magnetite alters to ferric hydrate and quartz. Chrysocolla forms when silica is plentiful; zinc minerals are not uncommon in these deposits, and efflorescences of the zinc and magnesia sulphates sometimes cover the tunnel walls. During the process outlined above, lime is almost wholly eliminated, while alumina forms residual concentrations.

**OXIDIZING PROCESSES IN SHALE.**—Disseminated cuprite in beds of Morenci shale is a common occurrence, and some of the large ore bodies of the Manganese Blue mine were of this character. It occurs as flakes on the bedding planes, or in small replacement veins, sometimes accompanied by distinctly later malachite and by limonite.

Azurite also occurs frequently in shale, as shown by the second ore body in the Detroit mine. Large crystals of that mineral develop here, metasomatically, in a metamorphic shale, composed of sericite

and amphibole. Cases have been observed where azurite envelops masses of undecomposed pyrite accompanied by a little limonite. During the oxidizing process, the alumina possesses considerable mobility. It is dissolved by sulphuric acid from clay shale and by decomposition of certain aluminous minerals, notably sericite. The aluminum sulphate formed is extremely soluble in water, and thus easily transported. At many places in the mines of Morenci, pure kaolin forms, together with azurite and malachite.

(TO BE CONTINUED.)

## Water Rights in California.

NUMBER IV.

Written for the MINING AND SCIENTIFIC PRESS by  
SAMUEL C. WIEL.

**HOW AN APPROPRIATION IS MADE (CONTINUED).**—The mere diversion itself without the intent to apply the water to a beneficial use will not, of course, be enough; as where water is diverted merely to drain the bed of a stream so that it can be mined. (7 Cal. 261.) But when all requisites are present the right to the water dates back by relation, as we have seen, to the posting of the notice. (C. C. 1418). The actual application and use of the water may then follow, but need not do so immediately; the right is already complete, and the failure to make use of it within a reasonable time (130 Cal. 290 at 296) is only evidence of abandonment, to be considered hereafter. (115 Cal. 496, 60 Am. St. Rep. 806, note). There must, however, be apparent ability to apply and use it as intended; otherwise, though the construction work will be completed, there will be no bona fide intent to use it for a beneficial purpose, which, as we have seen, is also an essential. The absence of an apparent ability to use the water at completion is evidence against the bona fides of the intent (which must have a reasonable foundation), as in the case of gathering water in a reservoir for mere speculation. (15 Cal. 271.)

There having been a proper notice, a bona fide intention to apply the water to a beneficial use, diligence in the construction work, and an actual completion of it, the right is complete, and dates from the posting of the notice. (C. C. 1418).

**EXERCISE OF THE RIGHT.**—We now leave the questions arising out of the obtaining of water rights and take it as granted that a valid water right has been obtained by appropriation, as previously set forth. The inquiry now is as to the limits within which the water can be then used. The limitations to be considered are (1) those arising out of the nature of the right; (2) those concerning the manner of use; (3) concerning the amount used; (4) concerning the purpose for which used and the place of use.

1. The right is in the nature of a grant of favor or franchise from the Government to use the water (6 Cal. 548 at 558; 75 Cal. 464 at 483); that is, it is usufructuary solely. There is no property in the channel itself, nor in the water itself, nor in the natural flow. As there is no property in the channel itself obtained by appropriation, the same channel may be used by several appropriators, as where one man had appropriated water and a later comer above stream poured water into the channel and then diverted it again before it reached the former appropriator, thus using the channel as a link in a long ditch line (7 Cal. 46; 11 Cal. 143). The ownership of the channel remains with the Government. As, in the next place, there is no property in the water itself, the appropriator cannot sue for the value of water diverted by another, but only for the damage to his own use of it (57 Cal. 44). Nor can he set up any claim to water after it has left his ditch (3 Cal. 249), the water itself not being his, but only the use of it, which is what is expressed by saying that the right is usufructuary solely. As, finally, there is no property in the natural flow, it is held that, so long as one's ditch is filled, a later comer may change the amount of the natural flow by taking the surplus (13 Cal. 220), or an artificial flow is enough if one's ditch remains, nevertheless, filled as usual (113 Cal. 182 at 196)—without causing uncertainty, it should probably be added.

Though usufructuary solely, the right is in the nature of real estate. In 5 Cal. 445 the court says: "From the policy of our laws it has been held in this State to exist without private ownership of the soil, upon the ground of prior location upon the land, or prior appropriation and use of the water. The right to water must be treated in this State, as it has always been treated, as a right running with the land, and as a corporeal privilege bestowed upon the occupier or appurtenant to the soil; and, as such, has none of the characteristics of mere personality." They held that a justice of the peace had no jurisdiction over an action for diversion of water, because it was an action concerning real estate.

It may become appurtenant to the land for which it is used, if any, and in such case passes with it as an appurtenance, if appurtenances are mentioned in a sale (47 Cal. 453; 93 Cal. 365; 75 Cal. 464), for "it can be transferred like other property" (13 Cal. 220 at 233). A sale of it requires a writing, because, being an interest in realty, it is within the statute of frauds (Griseza vs. Terwilliger, 28 Cal. Dec. 313). The

statute of limitations concerning land applies to it (25 Cal. 504).

But the water right is not held like land, absolute, in the full sense; it is held subject to conditions owed to the Government, from whom it is at the start obtained, the chief of which conditions is that it must be continually used for a beneficial purpose. An illustration of this condition of beneficial use, under which a water right is held, occurred in the very recent case of Griseza vs. Terwilliger, 28 Cal. Dec. 113. It was there held that a verbal sale would not pass a water right, as it is an interest in land requiring a writing; but it was held, at the same time, that it would be taken as evidence of an abandonment, signifying an intention to discontinue applying it to a beneficial purpose oneself, as the Government requires. It was even hinted that it was an abandonment ipso facto, which harsh result is not one of the usual consequences of a parol sale of real estate, nor, for example, of a parol sale of an unpatented mining location (51 Cal. 258). If the head note, in the "Decisions," to the Griseza case correctly represents the decision of the court to this effect, then the statement in 13 Cal. 233, that it can be transferred like other property, must be taken with limitations, and the owners of water rights would be in danger of losing them entirely by a parol sale or a faulty deed. At all events, it shows again that there is no title to the water itself; but the right is usufructuary solely.

2. Manner of use: It has been said that the appropriator may use the water in any manner necessary to carry out the use for which it was appropriated (46 Cal. 218). It is a rule applying to all branches of the law of waters that whether the use is by water wheels, taking it by pumps, using it in steam boilers, etc., makes no difference (111 Cal. 473). Under Sec. 1415 civil code, the means by which water is diverted may be changed later, so long as others are not injured by the change. The only important limitation upon the manner of use is that the water must not be used wastefully, for then it is not all used, for a beneficial purpose, as is necessary (C. C. 1411; 132 Cal. 312; 112 Cal. 230). This is the same under the doctrine of riparian ownership, also; e. g., in one case a riparian owner built a dam, spreading out the water over a flat for cattle to wallow in, so that much was lost by evaporation. He was stopped by a writ of injunction (28 Cal. 340).

The use by means of ditches and flumes is, of course, the most usual, and using it in this way does not, by any means, make the appropriator an insurer of others against accident from breaking ditches or overflows. There is a famous English case (Fletcher vs. Rylands, L. R. 3 House of Lords, 330) declaring that a man builds a reservoir, etc., at his peril. But such is not the law in California (10 Cal. 413; 35 Cal. 679). Nor does such a break or overflow in itself prove that the ditch owner was negligent; or, as it is said, it is not a case of "res ipsa loquitur," and negligence is not presumed (7 Cal. 335). The owner is liable only if the break or overflow occurred through his negligence, a failure to use the care which an ordinary prudent man would have taken with that ditch (10 Cal. 541).

3. Amount of Water: Before the code the appropriator could take to the full capacity of his ditch, having a reasonable time, after its completion, to remove obstructions, rocks, etc., and to remove other things causing an irregularity of flow. (8 Cal. 443). He was limited to that, however, and could not take more later, unless by a new appropriation. (13 Cal. 33; 21 Cal. 374). Under the code he must state in his notice how many inches of water he appropriates, and will be limited to that (C. C. 1415), or, if he uses less than that, to the amount actually used. (112 Cal. 230; 120 Cal. 86).

The surplus over what he has appropriated may itself be appropriated by later comers. (13 Cal. 33; 120 Cal. 86).

4. Place and purpose of use: Under the code, the place and purpose of use must be stated in the notice (C. C. 1415). What constitutes a proper purpose has already been considered under the question of intention, and it need only be inquired here what changes can be made in place or in purpose of use, without a new appropriation.

As to change of place of use: It was early decided that the place of use may be changed without loss of priority. It was absolutely necessary in the early mining days, when new ground was being continually opened up. In 7 Cal. 261 it was held that branches could be run to new mining claims without loss of priority, and that the main ditch itself could be extended to new localities. In 15 Cal. 161 it was held that the point of diversion or taking of the water could likewise be changed. The only limitation recognized on change of place by these cases and the cases following them was that others must not be injured in making the change. These rules are now incorporated in the civil code, Sections 1412, 1415.

As to change of purpose: This was at the start treated as a distinct question from change of place (e. g. 7 Cal. 261). It was urged in several cases that the right was limited to the purpose for which first appropriated and that a use for a new purpose could be obtained only by a new appropriation. This view obtained some footing in the early decisions (e. g. 13 Cal. 33, 21 Cal. 374). But it never took a firm hold. In 13 Cal. 220 it was held that use for a saw mill

could be changed to use for a grist mill, and in 32 Cal. 26 it was said (obiter) that use for placer mining could be changed to use for quartz mining without loss of priority. The more recent cases are in this line, though they do not go into the question closely. They disregard any distinction between change of place of use and change of purpose of use. It seems established that the rule now is that there is no limitation on either change of place of use or change of purpose of use, so long as others are not injured by the change (96 Cal. 214, 101 Cal. 242, 108 Cal. 72), though it should be noted that only change of place of use is specifically covered by the civil code.

That the place of use may be upon distant lands is one of the characteristic features of the law of appropriation.

**PROTECTION OF THE RIGHT.**—We have been considering, up to the present, what the appropriator has a right to do. Now it is proper to consider what he has a right to complain of; that is, what constitutes an infringement of his right by others. This is, of course, a wide field, of which we can here only look lightly into the most important principles. They are, that others cannot injuriously change the quantity or velocity of the water, nor its quality.

1. Others cannot change the quantity or velocity injuriously. Before the code, while others could take any surplus, they were bound to leave enough to fill the prior appropriator's ditch (8 Cal. 327). Under the code they must leave the number of inches called for in the notice, or what is actually used, if less than that (ante). Whether the later comer is himself an appropriator or a riparian proprietor, makes no difference, for as has been seen, later grants of land are all subject to the prior appropriation; even a later railway grant from the Federal Government (101 U. S. 274). The way in which the diminution is caused is not important; for example, if sawdust from a sawmill clogs up one's ditch so as to diminish the flow, it is actionable (23 Cal. 481). Or if the velocity is diminished by a dam preventing the working of a placer claim, provided plaintiff is prior in time (46 Cal. 118).

It may be that our appropriator was himself later in time than others, and so, himself, had a right only to the surplus. In that case his surplus will be protected as fully as though it were the entire flow, and prior appropriators who exceed the limitations already shown under "exercise of the right" will be acting unlawfully, as there shown; likewise prior riparian owners who are taking more than is reasonably necessary for cultivating or pasturing their land or for the other uses that are allowed under the law of riparian rights (102 Cal. 151, 69 Cal. 255). Those riparian rights, it may be merely mentioned here, include irrigation, running machinery, watering cattle, for all of which a reasonable amount. They include also domestic and household use, for which there is no limit in amount the riparian owner can take, and for this purpose the riparian owner can take all, leaving none, whatever, to come down to the later appropriator (69 Cal. 255).

At this point the question of percolating water arises again. What if appropriated water is drawn off by percolation? This is of great importance to miners, because their works are likely to drain wells and springs and even streams in the neighborhood. As an eminent authority says:

"In sinking a shaft through permeable ground it is, of course, necessary to lift continuously the ground water. The water level thus acquires an inclination towards the shaft, which may thus receive not only the flow of the immediate vicinity, but even also that of neighboring river systems." Posepny on Ore Deposits (A. I. M. E.), page 19.

Up to the present this was regarded as what the law called "damnum absque injuria," a damage the law did not think proper to look into; and such is the law in most States, and in England to-day. But the recent California decisions, already touched upon, on their face appear to establish the new rule that the owner of wells, springs or streams may maintain an action for this. A tunnel draining a spring was held unlawful in 142 Cal. 437. A tunnel draining the supply from a surface stream, even before it ever reached the stream, is unlawful (141 Cal. 275). And one draining off water after it has reached the stream is all the more so (Montecito vs. Santa Barbara 18 Cal. Dec. 405). And likewise water cannot be taken from wells (141 Cal. 116). These cases will cover probably all that will usually arise, unless, perhaps, the following: That is the withdrawal of water by a mine may dry up the neighboring soil itself. In the Nineteenth Annual Report of the United States Geological Survey, Part II, page 274, in an elaborate investigation of the movements of ground water, it is said: "In another part of this paper it was shown, from direct observations, that the withdrawal of a comparatively small amount of water from a soil already saturated is sufficient to produce a marked change in the level of the ground water, and hence to cause marked changes in the level of waters in wells, and in the height of the ground water in sections where crops depend on water which is derived from the underflow by natural sub-irrigation." If an action can be maintained against a miner for draining a well by percolation, it is only a small step to holding him liable for draining the soil of the water needed for crops in "natural sub-irrigation." It is one of the many phases of the new doctrine that must be dealt with, and shows that, if logically pushed, the principle of Katz vs. Walkinshaw, 141 Cal. 116, may make the miner an insurer to agriculturists against damage to crops, etc., from desiccation; with this proviso, it will be admitted that the miner will not be responsible for the results in extraordinarily dry seasons, or, as it is called, from a "vis major," or "Act of God."

When one further decision is considered, it appears that the law of waters has taken a form that leaves the miner at a decided disadvantage in controversy with his agricultural neighbors. Not only is the miner liable if the water is taken from wells, etc., but, on the other hand, he must suffer the percolation of waste water from irrigation into his mines, and has no right of action even if it comes through in such quantities as to prevent the working of the mine. It was so held in Gibson vs. Pucbta, 33 Cal. 310. The result seems to be that the miner must not take water from the farmer's land, but the farmer is not reciprocally bound to keep the water out of the miner's works.

Mr. Justice Temple's opinion in Katz vs. Walkinshaw turns on the motive with which the water is drained, and would give no action if taken in the "ordinary use of one's land." But the court in its final opinion (141 Cal. 116 at 129 discussing the case in 69 Cal. 217) says that it will be no defense to the miner that he made or wanted no use of the water, or that his works were made in the legitimate and ordinary mining of his own land, and it must certainly follow if the rule, so often repeated, that the motive with which an act is done is immaterial, is to be sustained. The actual decisions, so far, also, on their face, seem to support this view.

That the miner's motive, through which the water is drained away by percolation, will not be looked into seems, then, to have with it the tendency of the decisions. But it is by no means positively settled yet—it is one of the many phases of the new doctrine of percolating water that the case of Katz vs. Walkinshaw has thrown open, and that await decision. The wide statement that the motive with which an act is done is immaterial need not be sustained. It is giving way in other branches of the law, especially where injunctions are granted against malicious combinations in strikes and boycotts. It is inconsistent with Mr. Justice Temple's opinion in Katz vs. Walkinshaw; and it is inconsistent even with the irrigation case cited above, where the decision went on the ground that the defendant's motive arose out of the undoubted right to cultivate and irrigate his land. If the motive is looked into on one side, it should also be on the other. If the motive to make profit by cultivating and planting in the ordinary way justifies the farmer in irrigating, the motive to profit by mining in the ordinary way should justify the drainage of water naturally incident to that. Any damage which then occurs would lie where the nature of the land as mineral or agricultural makes it fall.

The difficulty if the miner is held liable will be great in showing that the acts of the miner in fact do draw off the water, since there are no signs above ground, or in plain sight, such as there are when a surface stream is tapped by a ditch. When it comes to showing an underground connection causing the loss of percolating water from a well, it is likely that we shall have the same elaborate and indefinite discussions that have surrounded the suits to protect extralateral rights to a vein; to show an underground connection between the ore in one's shaft and the distant works of a trespasser, has always been a difficult undertaking. It may be remarked that the matter has not yet come before the Supreme Court of the United States; but there are a number of decisions in other States resembling the decision in Katz vs. Walkinshaw. They are collected in 64 L. R. A. 255 note.

2. The quality cannot be changed injuriously by later comers. As against prior appropriators or occupants, the general rule prevents any injurious change in the quality of the water. Thus, it is actionable if a later miner so muddies a stream that it cuts the hose of a hydraulic miner below, who was prior in time (27 Cal. 475). Sawdust cannot be thrown into a stream if it interferes with prior appropriators (23 Cal. 481). Injunctions were granted in the following cases for wrongfully depositing waste in streams, plaintiff being in some cases an appropriator, in others a riparian proprietor, for both are protected from such damage: 34 Cal. 231, where waste from sluice mining interfered with a prior agriculturist; 43 Cal. 39, where tailings clogged another miner's tail-race; 67 Cal. 267, where sediment filled a prior appropriator's ditch; 19 Cal. 623, where debris clogged a prior appropriator's ditch; 57 Cal. 412, where debris from coal mining was carried far down stream and there, when the stream overflowed, covered agricultural ground. The court there said that the long distance made no more difference than if the debris had been dumped on the fields after being carried there by carts or cars. And there are numerous cases dealing specially with debris from hydraulic mining, because the sediment interfered with others. In 19 Cal. 623, 66 Cal. 138, 66 Cal. 161, 18 Fed. 753, 81 Fed. 243, 88 Fed. 664—in all these cases, and others, hydraulic mining was enjoined.

As a result of these cases, Congress has prohibited hydraulic mining, making it a misdemeanor, unless under permission from the "Debris Commission" (27 Stat. at Large 507). This prohibition is made to extend to whatever the words "hydraulic mining" or "mining by the hydraulic process" meant in California in 1893, when the act was passed. Whether it would include such things as working over tailings, or dumps, or artificial banks of earth, by water under pressure, is not clear. If one puts emphasis on the words "hydraulic process," as Judge Lindley does, then such work would be included (Lindley on Mines, 2nd Ed., Section 552, et. sq.). On the other hand, if emphasis is put on "mining," it might seem the other way; the washing of tailings is rather analogous to smelting or ore dressing, only incidentally following mining or extraction of ore. There seems an argument in saying that the act meant to hit at the principal, and not the incident when separated from it—at a kind of mining and not at a kind of process. In that case the treatment of material already mined is not, primarily, mining. Though following mining as an incident where the extraction and treatment are continuous, it is not strictly mining when the two are separated. It might not be within the act in this view, but would be left as at common law. The question seems one of emphasis in the use of the words, "mining by the hydraulic process," or "hydraulic mining."

The right to deposit waste in streams may, however, exist. It may arise by priority of right on public lands (7 Cal. 148), though priority will not sanction it if it amounts to a public nuisance (66 Cal. 138). The most important consideration, however, is that no one can complain of pollution of a stream if his own use, though prior, is not materially interfered with. The burden is on the plaintiff to show an injury, and so, for example, a placer miner can have no action where later comers above muddy the stream but still leave it fit for his purpose. (Atchinson vs. Peterson, 87 U. S. 507. Also 8 Cal. 327, 11 Cal. 143, 25 Cal. 481.)

The question of pollution of streams is one of great importance. The subject is treated at large in the recent bulletin of the United States Geological Survey, Number 103, Water Supply Series, and in Lindley on Mines, second edition, section 838 et sq.

3. Form of remedy. The owner of the water right has the usual recourse to the courts, as he has in the protection of any other property. The most efficient remedy is, of course, the writ of injunction, whereby interference is stopped forthwith. Among other requisites to obtain this, there must be a threat, or likelihood, of irreparable damage. An injury of a ditch which will not destroy its efficiency, and can be easily repaired, will not be enjoined—the owner will be left to his less drastic remedies. (35 Cal. 534). And another essential is, that the interference is, or is threatened to be, a continuing one in the future. An injury to a ditch already accomplished in the past is not a case for an injunction. (8 Cal. 392). A proper case was such as 23 Cal. 452, where some miners were engaged in works that were destroying a farmer's reservoir and ditch, and there still remained time to stop them. An injunction was granted. And in McCarthy vs. Gaston, etc., Mng. Co., 28 Cal., Dec. 377, a very recent case, an injunction was granted against pollution. In 17 Cal. 102 and 35 Cal. 534 an injunction was refused because of the rule known as the "balance of inconvenience," that is, because the injury to the plaintiff was small as compared to the injury to the defendant if his works were enjoined. Such a disproportion of inconvenience as to cause refusal of an injunction should not, however, depend on mere difference of money damage; the difference must go to the irreparable loss of some substantial right on the part of the defendant aside from money value, while the interference with the ditch, etc., causes but slightly such a loss to the plaintiff, leaving him substantially compensated if the defendant pays money.

Though every case of injury to a water right does not make a case for an injunction, it does make a case for damages; that is, money compensation. An interference with a water right is in the nature of a nuisance. (8 Cal. 77).

Other forms of action have been used. Very many suits have been allowed to quiet title to water rights, as to other property. (e. g. 130 Cal. 290). In Katz vs. Walkinshaw, 141 Cal. 116, it was said, in passing, somewhat in this line, that a suit will lie by a landowner to have his right to percolating water declared, though he has sunk no well or otherwise made use of it; but that will probably be a matter for further consideration if the case actually arises. If there are several claimants on one stream, the court will apportion it among the claimants, and adjust their rights thereto. (Miller vs. Dondero, 26 Cal., Dec. 211).

The remedy nearest at hand is, usually, a show of force on the part of the owner; and in a few cases this is quite proper. Reasonable physical force may be used always to keep off trespassers. In 75 Cal. 601, the court says this extends to a "molliter manus imposit," which, translated from the Latin, means "a gentle use of one's fists." Of course the law does not sanction serious bodily injury in putting a man off one's land.

4. Crimes: Under the penal code, there are the following crimes peculiar to this subject: Under Section 347, poisoning water in any spring, well or reservoir is a State's prison offense, and under Section 374 fouling the water by putting offal or filth into any

stream, pond, lake or reservoir is a misdemeanor. Under Section 499, stealing water from flumes, pipes, etc., is a misdemeanor. Under Sections 592 and 607, destroying or injuring flumes, reservoirs, etc., is a misdemeanor.

### The Cost of Diamond Drilling.

The subject of diamond drilling for prospecting purposes is known to miners almost everywhere, and yet there is much less of it done than its advantages seem to warrant. By systematic placing of the holes diamond drilling will give reliable information as to what lies in the rocks hundreds of feet distant in any direction that exploration is attempted. One reason, perhaps, that diamond drilling is not more generally employed is due to the unfamiliarity of miners generally with the equipment and operation of diamond drilling machines. These drills are of various sizes and shapes. Some are small, of light weight and readily portable from place to place in a mine, but are capable of drilling a  $1\frac{1}{2}$ -inch hole a distance of several hundred feet. Others are of large size, heavy, and can bore a hole several inches in diameter to the depth of a mile or more. Between these are many sizes and types of machines made by various manufacturers and suited to the differing conditions. The diamond drill can be employed on the surface for prospecting for ore, coal, stone or oil. It may be started in a river or on the beach, through water, or it may be taken into a mine, to bore from the bottom of a shaft downward or in any direction. It may be set up in a drift or stope and holes bored into the surrounding rocks in any desired direction. As a searcher for ore bodies it can be employed to great advantage, as the manager of the mine can inform himself at minimum expense of what lies on all sides of him.

In order to make prospecting of this sort valuable, the drill holes must be arranged systematically and a careful record of all work done made daily, and this should be carefully plotted on a mine map, in order to show the relative position of any valuable deposit cut to the existing workings of the mine. The diamond drill hole does not always maintain an absolutely straight alignment, it is true, but this is not important except in holes of great length. A hole will drift from a few inches to over 100 feet in 1000 feet. The cause of this in holes started vertically is difficult to understand, for in some instances the drill has drifted against a dipping formation, when naturally it would be expected to be deflected by it and the drill drift in the direction of the dip. In holes departing from the vertical, the tendency is for the hole to drift upward. A hole started absolutely level will in a few feet begin to point upward slightly, and this tendency increases with distance from the machine. This is due almost entirely to the fact that the drill bit containing the diamonds is a little larger than the pipe following it, which naturally bends slightly, causing the bit to be deflected upward. Though this at first be ever so little, in a hole 100 feet long the drift becomes very perceptible, and at 500 feet it is likely to reach 50 or 60 feet—that is, the bit at 500 feet from the machine will be 60 feet higher than where it started, though the hole was at the beginning perfectly level.

By a systematic arrangement of holes, the driller can usually correct for this deflection of the drill bit, so that its real position may be approximately known.

Another reason why diamond drilling is less popular than it is, is no doubt due to the impression that the cost of operation is excessive. That this is true is not the case, when the cost is compared with the expense of getting the same information by means of the ordinary drifts, crosscuts, winzes, raises and other mine openings.

In a Pennsylvania coal mine 4500 feet were bored at the rate of 19 feet per ten-hour shift at an average cost of \$1.37 per foot, the cheapest being a 500-foot hole at \$0.98 per foot.

In very hard ground the cost ranges from \$2.50 to \$3 per foot for holes of considerable depth. In Canada over 2600 feet were drilled at a cost of \$0.98 per foot.

At the Wildman gold mine, at Sutter Creek, Cal., John Ross Jr., the superintendent, reports that, in 1895, the cost of drilling per foot was as follows: Labor, \$0.561; carbons, \$0.396; other supplies, \$0.047; total, \$1.004. In 1899 the cost was as follows: Labor, \$0.322; carbons, \$0.091; other supplies, \$0.005; total, \$0.418. This was the lowest cost at which drilling was done at this mine, and, taking the total of 4255 feet drilling, the average cost was as follows: Labor, \$0.416; carbons, \$0.218; other supplies, \$0.039; depreciation of drill, \$0.021; total, \$0.694. In the adjoining mine 4136 feet of drilling was done during a period of three years. The average cost was: Labor, \$0.42; carbons, \$0.16; other supplies, \$0.04; depreciation of drill, \$0.053; total, \$0.673. This covers all the cost except for the power for the drill, and on the average a diamond drill of the size used does not require more power than an ordinary piston machine drill (about 10 H. P.)

This drill bored a hole  $1\frac{1}{2}$  inch in diameter and yielded a core  $\frac{1}{8}$  inch in diameter, and was capable of drilling a hole 600 feet deep. In diamond drilling the deeper the hole the greater the cost per foot.

### The Discovery and Development of Tonopah.\*

Prior to the discovery of the rich gold-silver ores of Tonopah, Nevada had, for some years, attracted little more than passing attention from the outside world. That fortunate discovery, however, soon awakened renewed interest in the possibilities of the practically unexplored region south of Belmont. Scores of prospectors, mining men, geologists and others had passed that way before, but the unpromising outcrops on the slopes of the volcanic hills which rise above the desert, where now stands the town of Tonopah, did not prove attractive to them, if they were observed at all.

California Co.'s Works, Tonopah, Nev.

This proves how unwise it is for prospectors to attempt to discriminate between what they consider good formation and what they believe to be poor, though this belief may be based upon actual experience gained elsewhere. It is said that J. L. Butler, the discoverer of Tonopah, gave some of the croppings to an assayer for test, and that this assayer, whose experience should have taught him better,

lites, various porphyries, basalt and glassy volcanics. There are also metamorphic rocks and abundance of limestone. That any of these rocks, except perhaps the basalts and glassy vitrophyres, are destitute of valuable mineral deposits would be an extremely unsafe premise for the prospector, for in the numerous mining districts of that elevated region valuable ore deposits are found in almost every mountain and ridge. Some of the most valuable mines ever found in Nevada have been in sedimentary rocks—as the great lead-silver mines of Eureka district. The famous bonanzas of the Comstock at Virginia City occur in andesite, some of those of southern Nevada in granite and schist.

In the immediate vicinity of Tonopah the rocks are andesite of varying age. These rocks are both mas-

sive and fragmental (tuffs). Surrounding the Tonopah section are sedimentary rocks—quartzite, schists, limestone, etc. The rich gold-silver veins of the district are found in hornblende andesite, over which lies a later deposit of andesite in which no mineral veins have been found. A great portion of the later andesite has been eroded, leaving the underlying older formation with its veins exposed. Had

Two Thousand Tons of \$15 Ore, Too Low Grade to Ship, at the Omera Mine, Tonopah, Nev.

after keeping the ore a day or two threw it out, as too unpromising to spend fluxes, time and fuel upon to determine its value. The first assays were made at Belmont, Nev., and various pieces of the rusty looking quartz assayed from \$50 to \$600 per ton in gold and silver. Mr. Butler quickly returned to the scene of his discovery and located the claims he thought most valuable, and his judgment has since been abundantly proven to have been good.

Because a certain kind of rock has proven to be non-productive of valuable veins or ore deposits in one region or locality is not sufficient reason that good mines may not be developed in a similar formation elsewhere.

In the region of the Great Basin there is a great variety of volcanic rocks—andesites, trachytes, rhy-

erosion not thus uncovered these ore deposits there is no probability of their ever having been found.

As indicating that the volcanic andesites burst through older sedimentary rocks underlying the former may be mentioned the fact that the andesites are often found to include fragments of limestone and of granite, which have been included in the andesite as it broke through from below.

That the region has been one of repeated volcanic disturbances is abundantly proven by the succession of rocks uncovered by erosion, and faulting has also been an important factor in the formation of ore deposits and in their economic distribution.

The value of the ore in the outcropping veins having become known, the development of the district was rapid. The principal claim, the Mizpah, was divided into thirteen sections and each section leased to a party of practical miners, who in a few months

\*See illustrations front page.

made many thousands of dollars by shipping the ores to distant reduction works, hauling the ore 60 miles across the desert to Sodaville, a station on the Carson & Colorado Railroad.

The sequence of the most important geologic events in Tonopah district are given by J. E. Spurr as follows:

SEQUENCE OF FORMATIONS AND EVENTS IN THE VICINITY OF TONOPAH.

- Early andesite.
- Fracturing.
- Vein formation. (Primary minerals, quartz, valenianite, stephanite, pyrite, chalcopryite?) Values good: gold and silver, silver predominant.
- Erosion.
- Later andesite.
- Probable erosion.
- Dacite.
- Dacite breccia.
- Rhyolite breccias, flows, and dikes, intermingled with slightly stratified or interstratified pumiceous or tuffaceous fragmental material.
- Vein formation. (Primary minerals, quartz, pyrite). Values relatively low; gold and silver, gold apt to predominate.
- Erosion.
- Tuffs, with an occasional thin rhyolite flow.
- Elevation of tuffs.
- Tilting.
- Basalt.
- Chief faulting. (Affects everything preceding).
- Rhyolite (white) intrusion (probably Ararat, Oddio, Rnshton hills).
- Vein formation. (Primary minerals, quartz, chalcodony, calcite, siderite, pyrite). Values low; gold and silver, gold apt to predominate.
- Erosion.
- Dacite intrusion (Butler, Brougher, Golden, Siebert mountains).
- Mineralization (chalcodony, manganese). Values slight to insignificant. Mud veins.
- Erosion.
- Glassy rhyolite flow (slopes of Oddio and Brougher).

The camp in a few weeks after the first discovery had become a town. The houses were not conspicuous, the inhabitants being at that time mostly dwellers in tents, which is the usual form of shelter in new mining camps everywhere.

The top works of the several leases were scat-

ter, the walls of which are composed of thousands of glass bottles, forming a veritable crystal palace. It is needless to say that the contents of the bottles has long since disappeared in the dry atmosphere of that region. There are several structures of this character in camp. But there are also numerous well-built handsome homes and merchandising establishments, as also well appointed and substantially built mine buildings. Tonopah has settled down from the feverish prospecting period into a substantial, though less exciting condition of business enterprise. Those seeking new fields with hope of a sudden fortune are gone southward to Goldfield, Crater, Bullfrog and other new camps, and there they will do, and are doing over again, what has already been done at Tonopah.

A third illustration (see front page) is that of the Hasbrouck mine at Gold Mountain, 6 miles south of Tonopah. The surface equipment is a model of simplicity. The two-post head frame, with a single set of back braces, the guides, bucket and crosshead, all indicate that the plant has been designed by an experienced and economical miner.

### Comparative Costs of Producing Copper.\*

With copper rising in price, with a greater demand for the same during brisk trade in the near future than the visible supply is capable of, under these circumstances it is interesting to see how costs of production have been lessened, and the scope of low-grade ores widely increased so that they can deliver their copper contents to satisfy this growing need. While studying the balance sheets of the principal mines of the world, as Rio Tinto, Mount Lyell, Calumet & Hecla, and the many big concerns operating in the United States, Mexico and elsewhere, we can highly praise the enterprise of the Tennessee Copper Co. for minutely publishing their costs per ton of ore treated and per pound of copper produced, and wish that the others, including the British Columbian companies, would be as public spirited. The benefit of publishing costs in detail is of the greatest advantage to each and every mine, as it creates a

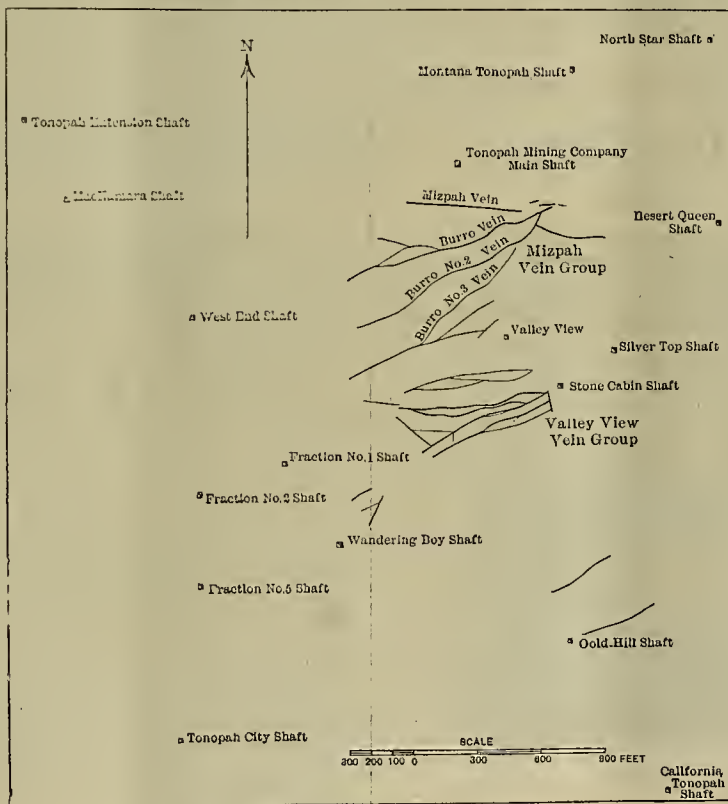

among other mines, have forty years ahead of ore blocked out for a daily consumption of 5000 tons. The grade of the ore is known, the costs of mining and treating are established, the profit is confirmed, and the possibility of cutting these costs still lower and making smaller slag losses, so increasing profits, is ever kept in sight. For their last fiscal year the Granby's output was 16,024,415 pounds of refined copper, with silver and gold to boot, from 516,059 short tons of their own ore treated, and over 40,000 short tons of custom ore and matte.

From a perusal of all the balance sheets published, it would appear that after the British Columbian record of \$1.35 per ton of ore treated in smelting and converting to blister copper, next comes the Tennessee Copper Co. with \$1.81 for the same results.

The Boundary ores dispense with all previous roasting, and use only lucrative value-bearing fluxes outside of coke, which account for the high duty of their furnaces, the first metal giving 50% copper, ready for converting to blister without a second previous fusion. These natural advantages are a great incentive to investment, and the hope of cheaper costs yet depends mostly on further railway competition and lower freight rates; extended communication with other large coal fields which are ready, waiting with keen avidity to market, at lower prices than now rule, their excellent fuel; and lastly, affording an even more extensive choice of lucrative fluxes to blend from the numberless copper fields known to exist. In fact, British Columbia is exerting herself to turn out immense tonnage of ore and coal, and to handle and treat that ore, by labor-saving devices, cheaper than is done elsewhere, taking advantage of the fluxing qualities in silica, lime, and metal to satisfy the chemical requisites for high duty and clean slags in the furnaces. Speaking of slag losses, all the companies are very diffident of publishing particulars; the general average is supposed to be three-tenths of 1% and more, equal to six pounds and over of copper per ton of slag. This, compared with the contents of the ore, seems wasteful, and the writer is still confident of his suggestion to use a reverberatory furnace as a forehearth to the blast furnace; then the slag will have space to allow the matte to more thoroughly settle, so bringing down the slag loss to one-tenth of 1% copper only; that it will also permit the use of the waste heat of the slags, in combination with the heat from the grate, to superheat the blast before entering the tuyeres to 1800° F., and reduce the consumption of coke from 12% to 5% and less.

The system of mining in the Boundary is open to criticism, not on account of its cheapness, for that is excellent, but on account of the factor of safety to the miners employed. In the open cast "glory holes" the machine drills operate to the supposed best advantage to blast down the ore. Sometimes a bluff is left, sometimes a slope covered with moving broken ore. Both situations are dangerous to the operators in setting up the drills, and it is questionable if it is not as cheap to mine in steps of about 20 feet deep vertically, and wide enough horizontally to allow steam or electric machine shovels to work in removing the broken ore. Explosives could be immensely economized, since all the holes, whether down or horizontal, will be the same length, and the quantity necessary to break without shattering would soon become known. Crushing by jaw breakers is cheaper than bulldozing with dynamite. According to local prices, the square-set system of timbering underground costs 35 cents per ton of ore extracted, a high item on low-grade ore. To avoid this cost, up-raises are put in on an average 25 feet apart, reaching from level to level 100 feet from one another, or to the intermediate levels half that distance. When these raises are ready a sufficient thickness of floor to hold up the track in the higher level is left—say, one set deep, then the ore is taken out from raise to raise from top down without timbering, and as wide across the deposit as the ore will come on a slope. The ore delivers itself into the chutes and is drawn off at all times as required, and to clear the slope; but as the slope goes farther and farther down from the roof, it is impossible for the miners to watch the roof for safety.

After blasting they start again drilling before all the smoke is clear, and before objects a short distance away are visible, for heavy loading in shooting is the rule, and so they take chances of a small piece or tons of the roof shaken by the last blast dropping on them. It cannot be long before a higher value will put locally on a man's life, and the present Government inspectors become competent and do their duty. This account is given to bring out suggestions for cheap mining combined with safety to the workers, either by individual protection in some iron-clad sentry box removed with the drill before blasting, or some other protection by timbering near the roof. Miners have already been granted by law an eight hours' shift. The smelter hands are jogging the local members of the Provincial Parliament for the same, and will probably get it. This, however, will only slightly affect the cost of smelting, since labor-saving feeders are being introduced and found to work well. This is a car holding two tons and side dumping; it travels singly as an electric tram, picks up from the chutes of the blast its weighed proportions of coke, flux, and ore, and dumps the whole mixture into the furnace; when humouring of a

Map Showing Vein System at Tonopah, Nev.

tered along the strike of the principal vein, and a somewhat primitive method of mining and of handling the ore was practiced. These scenes were being enacted during 1901-02, and have to a great extent ceased. The principal claims have been consolidated into corporate holdings and the mines are for most part well equipped and are being systematically developed. The headframe of the California company here illustrated is in striking contrast with the simple tripods of the early days in camp. There are also steel headframes of modern design on some of the mines, and Tonopah has emerged from a prospectors' camp into one of the prosperous up-to-date mining towns of Nevada, with a promising outlook for the future. The metallurgical question is still the all important one, as the ores do not yield their values readily to any process as yet tried upon them, but this is a detail which will probably soon be satisfactorily solved.

There are in Tonopah some oddities in architecture, one of which is illustrated on the front page. It is a res-

healthy rivalry and a beneficial pruning of extravagance. Bewick & Moreing have shown the good results of publishing costs in gold mining; why not others also in copper mining?

Secrecy and an unfamiliarity with methods in vogue make the public look askance at smelting concerns, as, if one manager fails them, they do not know the rudiments to be certain where the fault lies. This especially applies to British capital invested in Rossland and some parts of British Columbia. The public have to take or leave a prospectus, believing it implicitly or becoming canny, for they are unable to verify costs of smelting or have the details at hand as in gold mining.

This is a pity; for when you have immense deposits where you have established the average contents per ton, and have a long life ahead blocked out, what more legitimate investment can be asked for? For example, the Granby company in Boundary district,

\*R. C. Cambell-Johnston in London Mining Journal.

bad spot is necessary the antidote is carefully placed when loading, and then applied to the sore in dumping, so dispensing with all shovellers and trammers on the feed floor. The slags below are removed in five-ton slag cars moved by a narrow-gauge engine. The matte is tapped into a tilting kettle holding as much as ten tons of matte, constituting one charge, traveling from an electric crane to the converters, so that little labor is used in a smelting works.

If the public will become familiar with the essential details of cheap mining, cheap transportation, cheap smelting, judicious blending of fluxes, and sufficient capital to take the full profit of refining at the works, with the local manufacture of the product into wire, etc., if necessary, then copper shares are a most enticing form of investment at the present time, with long-lasting qualifications.

## Notes on Crushing of Metalliferous Ores in the Stamp Battery in Africa.

NUMBER III.

Written for the MINING AND SCIENTIFIC PRESS by  
F. C. ROBERTS.

The rock breakers in general use in Africa are the Gates and Comet gyratory and the Blake and Dodge oscillating, although these are by no means the only crushers on the market. The suspended Challenge automatic feeder is universally used.

The mortar boxes employed vary slightly in outside dimensions, according to the dimensions of the heads and shoes used, but the inside clearances remain practically the same.

The popular type of mortar is the F. O. C. No. 110 pattern, the interior dimensions and design of which are calculated to more readily assist in the discharge of the product than is the case with the older types.

The mortars are all furnished with false bottoms for compensating in the wear of the dies. Liners are also supplied, which are bolted to the ends and back of the mortar, thus protecting these areas from wear.

With but few exceptions, the "heavy" wire-cloth screen is used, the range in mesh being from 400 (20-mesh) to 800 (about 28-mesh).

The automatism of the feeders is obtained by the tappet of the central stem coming in violent contact with the feed rod, of which two types are used, viz., the "straight rod" and the "goose-neck." Hardwood guides are almost exclusively used.

The stems are of steel and vary slightly in dimensions. Those used in the latest mills are 3½ inches in diameter and 16 feet in length, tapered at both ends to allow of reversing.

The cost per ton of ore milled in Rhodesia for stems is .1044 cent.

Cast steel tappets and heads are used, the former varying only in bore, while larger variation is shown only in the dimensions of the latter.

From an extended series of experiments carried out, it has been found—at least, with Rhodesian ores—that the manganese steel shoes and dies give the most economical results. The cost of these spare parts in Bulawayo is \$9.70 per 100 pounds weight, or .096 cent per pound.

The life of a manganese steel shoe having the following dimensions, 9 inches diameter by 12 inches deep, when crushing ordinary hard quartz, has been found to be ninety days, i. e., when reduced to a thickness of 2 inches. No realization on scrap iron or steel is possible in Rhodesia. The consumption of steel per ton of ore crushed was .52 pound and the cost per ton .0554 cent.

The dies of the same material, 9 inches diameter by 7 inches deep, used under the same conditions, lasted for the same period, the consumption of steel per ton of ore crushed being .27 pound and the cost per ton .027 cent, or slightly less than one-half the cost of shoes.

Cast steel cams of the Blanton type are used, the breakages representing a cost per ton of ore milled of .01 cent. Should the web of the cam be slightly increased in thickness, breakages would seldom, if ever, occur in a well-regulated mill.

The cam shafts employed are of forged steel, 6½ inches in diameter by 7 feet long. The breakages are due to crystallization and represent a cost of .0316 cent per ton of ore milled.

The earlier mills erected in Africa were of the lighter type—stamps varying from 700 to 900 pounds in weight when new. The tendency for the past eight years has been towards a gradual increase in weight, until now there is more than one mill installing stamps weighing 1445 pounds. Up to quite recently the popular weight was 1258 pounds, made up as follows:

Stem.....	Pounds.....	604
Head.....	284	
Shoe.....	285	
Tappet.....	135	
Total.....	1,288	
Die.....	134	

The weight of the heavier stamps is made up as follows:

Stem.....	Pounds.....	604
Head.....	437	
Shoe.....	299	
Tappet.....	135	
Total.....	1,445	

It is a question open to much discussion whether the practice of employing such heavy stamps is fully compensated for in increased capacity. It is, of course, almost impossible to obtain accurate comparisons in the capacity of two mills—one, say, of 1250 pounds and the other of 1465 pounds—that is, where all of the factors are identical; but it appears to the writer that the economic limits have been reached in the weight of stamps, if this point has not already been passed, and certainly the recorded duties of the heavier mills—in instances where, as far as one can judge, the working conditions are equal—show little or no improvement over the 1250-pound stamp.

It would appear that there is considerably more scope for improvements in other directions for increasing the crushing capacity of the stamp mill.

The theoretical consumption of power required to operate the stamp varies with the weight of stamp, the height of drop and the number of drops per minute.

The popular method of operating the mill in Africa is as follows:

Order of drop, 1, 3, 5, 2, 4.

Number of drops per minute, 96.

Height of drop, 8 inches.

Thus with the 1250-pound stamps the power required would be as follows:

$$\frac{1250 \times .66 \times 96}{33,000} = 2.4 \text{ H. P.}$$

$$\text{Add } 33\frac{1}{3}\% = 3.2 \text{ H. P.}$$

While with 1465-pound stamps the power required would be as follows:

$$\frac{1465 \times .66 \times 96}{33,000} = 2.8 \text{ H. P.}$$

$$\text{Add } 33\frac{1}{3}\% = 3.7 \text{ H. P.}$$

The formula, by H. Louis, given below, is largely used:

S = number of stamps driven off one shaft.

M = weight of cam shaft cams and pulley in pounds.

d = diameter of cam shaft in inches.

W = weight of one stamp in pounds.

h = height of drops in inches.

n = number of drops per minute.

k = radius of cam hub in inches.

r = distance between centers of cam shaft and stamp stem in inches.

$$\frac{S n W h}{12} + \frac{(S n W h)}{360} + 0.08 \left\{ S n W \left( \frac{2 k h + h^2}{24 r} \right) \right\} + \left( M + \left( \frac{h S}{n r} \right) W \right) d n$$

$$\frac{180}{33,000}$$

The consumption of fuel (wood) on a well arranged plant in Rhodesia should not exceed .05 cord per horse power per twenty-four hours. The cost of fuel shows some variation, but \$7.20 per cord would be a fair average. Basing the calculation on a 5-ton per stamp duty, the consumption of fuel per ton of ore crushed amounts to .032 cord, while the consumption of fuel per stamp of 1250 pounds would be .16 cord. The cost per ton of ore crushed for fuel alone is \$0.2304.

The most common type of boiler used in Rhodesia is the multitubular externally-fired boiler. This design is particularly adapted to countries where an inferior bulky fuel is used. In rare instances the Babcox & Wilcox water tube boiler is used. On the Rand fields a very wide variety of boilers are used, the last-named boiler being a popular one. Where the requirements are small the loco type boiler is used; but beyond, say, 30 H. P., these boilers are both extravagant and unsatisfactory.

The metallurgical treatment of an ore may be said to begin with the first sizing of the product as it is delivered from the mine. As the process of cyanidation or chloridization will not be dealt with, a resume of that common to that stage only will be given.

The sequence of treatment may be summarized as follows:

1. Sizing.
2. Sorting.
3. Crushing.
4. Milling.
5. Amalgamation.
6. Concentration.
7. Classification (sands).
8. Classification (slime).
9. Cyanidation (sand).
10. Cyanidation (slime).

We will premise a plant with a separate crusher station.

The ore as it is hoisted or trammed from the mine is automatically dumped over grizzlies set at an angle of about 50° to the horizontal. The usual spacing of the bars is 2 inches, the outside dimensions of the grizzly being 7x5 feet. Where large rock-breaker capacity is provided, it is advantageous to set the bars with spacings 1 foot wide, so that a finer product is conveyed to the bins.

The under-size product (fines) is conveyed direct to the mill bins by means of trucks, skips or belt conveyors. The over-size (coarse) is sometimes subjected to very coarse crushing—which process is not desirable when handling any appreciable quantity of waste rock—or is at once passed on for sorting.

The sorting arrangements embrace the revolving table, traveling belt or ordinary flat sheets. The importance of rigidly enforcing this branch of the work is recognized on the Rand fields, but in Rhodesia a large demand is made for everything coming from the mine, with the result that many tons of barren rock are milled.

Probably the most economical, if not the most effective, method of sorting is accomplished with the revolving table, which allows of an economical distribution of labor, very little wear and tear and a small consumption of power. The traveling belt has come into favor during the past few years, and certainly when it is desired to elevate, within certain limits, or to convey the product, this latter device is preferable to any other. In some cases on the Rand fields, where a large proportion of the narrower reefs are being mined, as much as 42% of the delivered product is discarded.

The importance of producing a product as nearly uniform in size as is consistent with economy can not be too strongly emphasized, and, with this object in view, double crushing is largely practiced. From the sorting table or other arrangement the ore is conducted to No. 1 crusher, where it is reduced to about a 2½ inch ring. It is then dropped over grizzlies, the under-size being delivered to the fines bin, while the over-size is conveyed to No. 2 crusher, where it is reduced to about a 1-inch ring, delivering direct into the fines bin.

This preliminary crushing might be extended economically by the introduction of a third crusher and possibly an intermediate grizzly, since the stamp mill seems only within certain limits to be the more economical method of reducing the product to its final state. With the entry of the ore to the mill bins begin the considerations directly effecting the extraction of the gold values.

(TO BE CONTINUED.)

## THE PROSPECTOR.

The mineral specimen from Tulare county, Cal., is volcanic ash and consists of microscopic fragments of feldspar, with occasional small scales of muscovite mica. It is not Fuller's earth.

The green specimen from Manvel, Cal., is chrysocolla (copper silicate), not turquoise. The black rock is augite andesite and the bright mineral flakes in the quartz rock are specular iron. No galena or other form of lead present.

The mineral specimens from Prescott, A. T., are: No. 1. Metamorphic clay slate impregnated with pyrite. No. 2. An altered granite probably from near the slate. No. 3 is an ore in which are visible iron, copper, lead and zinc sulphide. It probably contains gold and silver as well. The yellowish-green stain on No. 4 is due to the decomposition of an arsenical ore, probably mispickel.

The rock specimen from Weaverville, Cal., is metamorphic sandstone containing grains of cinnabar. A large body of this ore would pay to work for the quicksilver.

The mineral samples from Rossland, B. C., have been determined as follows: No. 1. (White.) Is granular quartz with marcasite and a little zinc blende. No. 2. A metamorphic rock in which is disseminated a considerable percentage of pyrrhotite (magnetic iron sulphide). It also contains a large amount of magnetite in finely disseminated grains.

The rock samples from Homestead, Or., are determined as follows: No. 1. A finely-granular quartz rock, stained with iron oxide. No. 2. Pyrolusite (manganese oxide) with wad (an impure ore of manganese and iron oxides). No. 3 is calcite.

The rock sample from near Marysville, Mont., is a crystalline granular limestone, the brown color being due to iron oxide.

The ore from Granite, Grant county, Oregon, is quartz in which is disseminated, in dust-like particles, iron sulphide. These are so numerous in places as to give the rock a bluish color. Galena (lead sulphide) is also seen, and there is present small particles of reddish iron-black mineral with a blood-red streak, which may be ruby silver (proustite), a combination of arsenic, sulphur and silver, or pyrrargyrite, a composition of antimony, sulphur and silver. The grains are so small and occur in the rock so sparingly as to be indeterminate.

The rock specimen from Lamar, Colo., is a dense, closely compacted sandstone. It is made up almost entirely of rounded quartz grains. The reddish-brown bands are due to iron oxide.

The light brown earthy material from Tacoma, Wash., is infusorial earth. It has absorbent properties and was formerly extensively used in the manufacture of nitro-powder, but is less used for that purpose now.

## Chlorine in Metallurgy.\*

Written by JAMES SWINBURNE.

The essence of metallurgy, as practiced for thousands of years, is the reduction of the oxide of the coveted metals with carbon, as such or as monoxide. Some metals, notably iron, exist in nature ready as oxide, but most of the others are found as sulphides. The sulphides are, therefore, roasted to convert them into oxides, and the oxides are reduced with carbon. Modern metallurgy broadly consists of the reduction of oxides to the metallic state.

The process I have the honor of bringing before you depends on the action of chlorine. Chlorine has been used in metallurgy before for attacking metallic gold; and salt has been employed for "chloridizing" roasting. The present process is, however, a new departure, of quite a different kind, and really a new form of metallurgy calculated to displace the oxidation and reduction processes now in use to a great extent. How far the replacement will take place depends eventually on economy only.

The principle of the process is treating sulphide ores, without previous roasting, with chlorine, so as to form chlorides of the metals, the sulphur being liberated as such. The chlorides are then electrolyzed, yielding metals and recovering the chlorine. The chlorine thus goes round and round, and the process in its simplest form is analogous to separating the sulphur from the metals electrically, and changing the ore, at the mere expense of electrical energy, into its component metals and sulphur. This can in fact be actually done. In one of my first patents there is a description of electrolyzing a bath of, for instance, zinc chloride and zinc sulphide, with carbon anodes and fused zinc cathode. This gives off zinc at the cathode and pure sulphur, not chlorine, at the anode. This simple method is not applicable to many ores on account of gangue, iron and other metals. It is mentioned to give a clear idea of the essence of the process.

In practice there are further modifications. The process naturally gives the best commercial returns on ores that are refractory to other treatment; and complex ores yield mixtures of chlorides and gangue which could not be electrolyzed straight off without intermediate treatment. The intermediate treatment is always simple chemically, and consists in removing the gangue and substituting zinc for the other metals, one after the other, till there is nothing but chloride of zinc left. The chloride of zinc is then electrolyzed and the zinc and chlorine recovered. If there was no zinc in the ore, all the zinc obtained is used up again; but if there was zinc in the ore it is sold as zinc.

The action of chlorine on sulphides is generally very vigorous and enough heat is generated to keep the mass hot. The transformer is something like a small cupola. It is an iron vessel lined with firebrick and it contains mixed chlorides fused carrying the gangue and ore. The ore is run in at the top continuously and chlorine is pumped in at the bottom; sulphur coming off and passing over into a condensing chamber. There is no difficulty about pumping chlorine. Iron cylinders, pistons and valves are employed, and, as is well known, though not fully realized, dry chlorine, such as that from the electrolysis of fused chlorides, is a very harmless gas.

The transformer is tapped at intervals, and the mixed chloride and gangue run into water. Broken Hill slimes, a waste product daily becoming more mountainous, have been chosen to work upon. They contain zinc, lead, iron, silver, manganese, sulphur and gangue. The gangue and lead chloride come together, and the lead chloride is separated, the silver extracted and the lead chloride electrolyzed. The soluble chlorides are treated with chlorine, to get ferrous into ferric chloride, and the iron precipitated with zinc oxide or calamine. The manganese is got out separately or with the iron in a similar way. The zinc chloride is then boiled down and electrolyzed. The electrolysis vat is simply an iron case lined with fire brick, and is kept hot by the excess of the electric over the chemical energy.

The history of the process is simple. The first patents were granted in 1897, and the process tried in the laboratory and everything worked well. It was then tried on a pound scale and worked. A plant was taken in Milton, and large scale experiments on electrolysis and handling of chlorine were carried out. A 3000-ampere electrolytic vat was run continuously for three months. Facilities were wanting there. A. J. Smith, the general manager of the Castner-Kellner Co., saw a chance of a future in the process, and the company made arrangements for us to put down an experimental plant next door to its works. This was done and the transforming was proved on a large scale.

We have repeatedly learned from the technical journals that the chlorine reaction does not take place, and that fused zinc chloride cannot be electrolyzed. In fact people have proved it with test tubes. The Castner-Kellner Co., however, was able to investigate the working of the process, and to inspect the transformer consuming at the rate of thirty tons a week. It was well enough satisfied with the results

to arrange to take the works over, acquiring a license to make chloride of zinc. It thus uses the whole process except the electrolysis, as they have a supply of chlorine from the soda works. It will run a 10,000-ampere vat for demonstration, but otherwise will sell every metal but zinc, the zinc being sold as chloride. The only difference in the process is that zinc chloride must be much more highly refined for the market than for electrolysis, as a trace of manganese, for example, would spoil the color, but would do no harm in electrolysis. The chlorine is also damp, and has to be dried before being pumped.

A good deal of work has been done recently on the treatment of ores with little metal content, such as copper ores running under 3%, and copper, nickel and cobalt ores. These modifications have only been tried on the small scale, and so it is too soon to speak yet, but apparently low-grade copper, nickel, cobalt, and, of course, their mixtures, and copper-zinc ores of low content, will prove amenable.

## The Confidence Mine, Tuolumne Co., Cal.

One of the noted mines of the East Lode of California is the Confidence, situated about 12 miles east of Sonora, in Tuolumne county. This mine was discovered thirty-five or more years ago by prospectors coming into California over the Sierra Nevada from Nevada. The croppings were observed in the coarse reddish granite a short distance from the trail, and several claims were located on the series of veins which comprise the outcrop. It is at an elevation of 4000 feet, not far from the metamorphic slates and schists of the Calaveras formation. The vein system strikes north 14° west, dipping easterly at 18° to 30°. In the early history of the mine the rock was rich and the output large, said to have exceeded \$5,000,000. In size the vein varies from a few inches to 15 feet or more. In some portions of the property it splits up into several veins of variable size. The granite in which this vein system occurs is coarse and stained red with iron oxide, beside which the orthoclase feldspar has a red or pink color. This granite is decomposed to a depth of about 300 feet in the vicinity of the vein. Below 300 feet the granite is firm and hard, and approaches more nearly in appearance and composition to the normal grano-diorite of the Sierra Nevada. Usually a felsitic dike rock of light greenish color, due to dissemination of chlorite, is an accompaniment of the vein. Although developed below 1000 feet, the mine makes comparatively little water—about sixty gallons per minute. The mine has been extensively operated and is well

cutting and threading pipe from ½ inch to 4 inches in diameter. The pipe is inserted in the barrel at E, bushings being furnished so that long lengths of pipe may be kept well centered in the barrel. These bushings are set in the end of the barrel and held fast by a thumb screw. The pipe is clamped in place between serrated vise jaws by means of a key at the

Pipe Threading Machine.

sliding head C, and the same key, at D, is used for locking or unlocking the threading die. A rack and pinion, operated by the wheel F, moves the sliding head C back and forth, the operator moving the wheel F to the right in order to feed the pipe into the die head. The cut shows the hand-power type of machine, in which the large drive wheel A is used to revolve the heads. This shaft moves in a sleeve, and by pushing it inward toward the machine it engages the beveled gears at the back and revolves the relatively high-speed head at C. By pulling it outward it engages the beveled gears in the front of the machine and moves the slower motion die head D. In a central position, it moves both heads in opposite directions. Where small pipe is being threaded, the drive wheel is thrown into its central position and the two heads move in opposite directions, giving the maximum speed. For intermediate pipe, the driving shaft is locked in the position closest to the machine, driving only head C and leaving the cutting head

Confidence Mine, Tuolumne County, Cal.

equipped with mining and milling plant. The metallurgical experiments made at this mine in the way of concentration and cyanide treatment forms an interesting chapter in the history of the mine.

The ore is quartz and is generally considered free milling, but the sulphides are high grade and difficult to save because of their tendency to slime. To save these slimes canvas plants have been successfully employed. The slimes resulting from the ultimate classification and concentration of the tailings often run upwards of \$1000 gold per ton.

It is stated by the superintendent, N. Carmichael, that the total recovery of values is about 90% of the assay value. Of this 50% is by amalgamation, 16% by the various methods of concentration and 34% by cyanidation.

## Pipe Threading Machine.

Herewith is illustrated a pipe-threading and cutting machine, built by the American Pipe Threading Machine Co., 200 S. Clinton street, Chicago, Ill., which has three changes of speed and has a range of

stationary. Where very large pipe is being threaded, the shaft is locked in a position where only the cutting head at D revolves, the pipe remaining stationary in the clamp head C. The rack and pinion actuated by wheel F gives the head a travel of about 8 inches, being sufficient to feed the pipe to the die for a continuous thread of that length; but provision is made for threads longer than 8 inches by releasing the vise jaws and back head C as far as possible, tightening the jaws and operating as at first, making another cut of 8 inches. This can be continued indefinitely. The hand crank wheel at A may be taken off and replaced with a pulley where belt power is desired.

The length of the day, that is, one complete revolution of the earth on its axis, is 23 hours, 56 minutes and 4.09 seconds. This interval of time may be measured with absolute accuracy by the passage of a fixed star past the range of two fixed objects. Engineers who have no other means at hand have sometimes taken advantage of this knowledge to regulate watches and chronometers.

\*Trans. Int. Elec. Congress.

## Mining and Metallurgical Patents.

PATENTS ISSUED DECEMBER 27, 1904.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

METHOD OF RECOVERING PRECIOUS METALS FROM SOLUTIONS.—No. 778,348; I. Anderson, Prescott, Ariz.

Process of recovering precious metals from cyanide solution and regenerating cyanide solution by introducing into cyanide solution radicals with which precious metals will form compounds insoluble in solution of potassium cyanide, then adding sulphuric acid to solution to precipitate insoluble compounds of precious metals, separating solution from precipitate and regenerating cyanide solution by precipitating sulphuric acid present by means of addition of lime.

BRICK KILN.—No. 778,441; J. C. Boss, Elkhart, Ind.

In combination, in kiln, arch, air box at bottom of arch, box being formed of brick, fire bricks resting on air box and slightly separated from each other to provide elongated openings extending transversely of arch, and mortar arranged at ends of elongated openings and between fire bricks, mortar sloping outwardly from lower part of fire brick to top to provide flaring discharge mouths.

HYDROCARBON BURNER.—No. 778,443; C. F. Capell, Los Angeles, Cal.

Hydrocarbon burner having frame, vaporizing chamber composed of three vaporizing tubes alternately connected together at opposite ends in frame and having ends projecting through frame; liquid fuel inlet at one end of tubes and vapor outlet at other end of tubes; non-inflammable cords in tubes; removable plugs in ends of tubes; vapor tube having channel having two outlets connected with vaporizing chamber, last vapor tube being surrounded on three sides and at top by frame; removable plate in frame surrounding ends of tubes comprising vaporizing chamber; small mixing chamber under ends of tubes adjacent to vapor outlet and provided with slots in top thereof and one in edge thereof adjacent to vapor tube; larger mixing chamber under tubes having central space with radiating channels extending therefrom, radiating channels and top being

slotted; air tubes connected to mixing chamber to receive discharge of vapor from vapor outlets.

AIR SEPARATOR FOR CEMENT GRINDING MILLS.—No. 778,452; H. Hitzel, Alpha, N. J.

In cement grinding mill, settling chamber arranged at top of mill and outside of mill proper, air exhaust apparatus located within mill above grinding path arranged to discharge cement-laden air into settling chamber, air inlet located below exhaust apparatus and above grinding path, partition within settling chamber against which air from inlets is discharged by exhaust apparatus, and cover of fine netting for top of settling chamber.

HOISTING APPARATUS.—No. 778,502; L. Moss, New York.

Combination with hoisting apparatus comprising hoisting bucket and means for operating same, receiving and discharge hoppers, and auxiliary carrier extending between hoppers, of removing conveyor independent of hoisting apparatus and arranged to receive material from discharge hopper.

DREDGER.—No. 778,634; William A. Collins, Bloomfield, N. J.

In dredger combination with boom, dipper and dipper handle, of operating chain secured to dipper and passing over outboard end of boom, means for operating chain, box secured to boom and provided with lug, radial arm carried by boom and sliding in box, having its outer end bearing on operating chain between dipper and outboard end of boom, and being adapted to regulate working angle of operating

chain, arm having series of recesses adapted to receive lug, lug and recesses being adapted, when in engagement, to resist thrust of operating chain when arm is in operative position, and means adapted to close all but one of recesses against engagement with lug.

ROTARY CEMENT KILN.—No. 778,611; G. H. Sharp, Jonesville, Mich.

In rotary cement kiln combination with outer casing adapted to be rotated, of cylinder arranged within, and secured to casing, cylinder having inwardly and outwardly projecting shelving attached thereto, and casing having inwardly projecting shelving, shelving having its end turned upward at about right angles thereto, means to feed material to casing and cylinder, and means to rotate casing.

GAS PRODUCER.—No. 778,614; S. T. Wellman, C. H. Wellman and J. W. Seaver, Cleveland, O.

Combination in gas producer, of hollow stirring or agitating arm, rotating element of producer carrying same and having partition whereby it is divided into two chambers one of which communicates with hollow arms, pipes projecting into hollow arms and communicating with other of chambers, and means for supplying water to one of chambers and conveying it from other.

ART OF REDUCING ALUMINUM OR OTHER METALS.—No. 778,100; H. S. Blackmore, Mount Vernon, N. Y.

Process of reducing metals by exposing compound of metal to be reduced to action of substance having such superior affinity for electro-negative constituent of compound that heat is evolved in reduction and simultaneously employing heat to elevate other ingredients capable of reducing metal by endothermic reaction to temperature at which reduction is accomplished, and carrying on reduction by action of such ingredients.

ONE of the latest innovations in mining equipment is an air rock drill which is operated by an electrically driven air compressor situated a short distance from the working face, where the drill is in operation. The mechanism is not complex, but is a radical departure from other types of either compressed air or electric drills. The main features of this idea have been in use for some time past in Germany, but in the latest adaptation of this novelty no air receiver or storage reservoir is employed, the air used being kept in circulation and continually reused.

## MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

### ARIZONA.

#### Gila County.

The Old Dominion smelters at Globe produced about 15,500,000 pounds of refined copper in 1904. It is thought that within four months all the surface improvements about the new shaft will be completed; also the 300-ton concentrator and the briquetting machines at the smelter for handling the blue dust. The smelter building is to be extended and a third converter stand and another electric crane put in, allowing the operation of three furnaces. The coke bin capacity above the smelter is being enlarged by extending the trestle 54 feet, which will give room for three more bins. The 70x17-foot concrete converter slag yard, with a floor of 2-inch iron plates for cooling the slag is almost done. The hoist is being moved forward 30 feet and 10 feet to the east. The pit and foundations for the belt conveyor, rock crushers and rolls have been finished; also eight steel ore bins south of the boiler house.

J. B. Coplen will superintend work on the Inspiration Copper Co.'s property at Globe. Two blowers, two gasoline engines, cars, track iron, etc., have been ordered.

The Trl-Bullion M. Co. has struck ore 7 miles south of San Carlos agency. In the main 1000-foot tunnel, a 12-foot lead was cut, carrying carbonates of copper and values in lead and silver.

#### Maricopa County.

(Special Correspondence).—L. R. Legier has men working his lead property northwest of Phoenix. Ore will be shipped to the smelter.—H. G. Bennett will put in a hoist, compressor and other machinery on his property near Morristown. The Mormon Girl mill on Cave creek is running full time on ore from the Mormon Girl mine.—Walker & Dunlap are having considerable work done on their property in Cave Creek district.—Work at the Relief mine is progressing in a satisfactory manner. The mill is in operation.—C. E. Philes is taking out ore from his Cave creek property which he will have milled.—J. Hauxhurst has gone to his copper property in the Osborn district, west of the Vulture mine.

Phoenix, Jan. 3.

(Special Correspondence).—The construction of a railroad from the Santa Fe, Prescott & Phoenix Railroad, above Wickenburg, towards the Colorado river is putting new life into the Wickenburg district. A smelter site below Wickenburg has been purchased and various properties in the district are being sampled. A number of properties around Wickenburg have recently changed hands.

Wickenburg, Jan. 2.

#### Pinal County.

J. Champion, superintendent of the Columbia Bell and Martinez, is thinking of putting up a concentrator and reduction plant and an aerial tramway at Cochran station, near Florence.

#### Yavapai County.

S. C. Symons, of the Verde Water & Power Co., is in Prescott regarding supplying of electric power for mining and other purposes from a plant at Parker's Butte, below Horseshoe reservoir, 75 miles from Prescott, which will generate 20,000 H. P.

At the White gold mine on the Hassayampa, 12 miles above Wickenburg, there are fifty men developing grading for a 20-stamp mill, cyanide plant and air compressors, and building a road between the mine and the S. F. P. & P. railroad. President Agnews of Valparaiso, Ind., is directing operations at the mine.

### CALIFORNIA.

During 1904 California produced 27,638 flasks of quick-silver.

There are fifteen oil fields in California. Statistics for September show:

	No. Productive Wells.	Output in Barrels.
Kern River.....	600	1,465,882
Coalinga.....	138	470,887
Santa Maria and Lompoc.....	18	46,380
Los Angeles.....	107,314	110,314
Fullerton.....	106	109,303
Puente.....	33	3,025
Whittier.....	83	40,245
Newhall.....	65	11,690
Ventura.....	255	49,475
Summerland.....	199	9,870
Sunset.....	31	21,650
Midway.....	33	Unreported
McKittrick.....	65	192,200
Sargents.....	3	6,150
Halfmoon Bay.....	...	...
Totals.....	2,763	2,546,081

It is estimated that the total petroleum output of California in 1904 amounted to 30,000,000 barrels.

There are three pipe lines carrying oil from California fields. The Standard Oil pipe line from Bakersfield to Point Richmond is nearly 300 miles long; the Coalinga pipe line to Monterey is 110 miles, and the pipe line carrying the output of the Santa Maria oil fields to tide water is 40 miles long.

#### Amador County.

The Ione & Eastern Railway Co., constructing from the terminus of the Southern Pacific at Ione to Sutter Creek and Jackson, has more than half completed its line and will extend it from Sutter Hill past Pine Grove and Volcano to timber which can be used in the mines at a price less than charged in San Francisco.

J. S. Smith of Sacramento proposes to build an electric line from Sacramento to Sutter Creek, past Elk Grove and through the Cosumnes valley.

#### Butte County.

A shaft is being sunk on the property of W. P. Lynch, near Pentz, for dredger prospecting purposes instead of drilling.

#### Calaveras County.

Ambleton Bros. & Co. are building a small quartz mill near Vallecito to crush rock from a pocket vein recently found.—A hoisting engine and boiler are being put up at the Barnasconi mine, near Fourth Crossing.

Near the Stanislaus river below Collierville, 6 miles east of Murphys, the Bourbon M. Co. has acquired water rights along the river and intend to transmit power into Sonora and other points by July. B. Thompson is the general manager. P. Copella of Douglas is local superintendent.

#### Mariposa County.

Near the Mariposa Estate, owned and operated by the Mariposa C. & M. Co., at Mount Bullion, Mariposa and Bagby, the Omparisa G. M. Co. is installing machinery at the Mountain King group, on the Merced river. A gravity tramway has been completed from the main tunnel to the millsite, a flume to carry water for the generation of electricity is being constructed, and the machinery for a large stamp mill is arriving.

At the Sweetwater mine new machinery and a 10-stamp mill have been received. In the old Quartzburg district, idle for years, capital has recently taken hold of prominent claims, among which are the Mount Gains, Exchequer and others. At Benton Mills, on the Merced river, the Mariposa C. & M. Co. is prospecting and running the old river tunnel toward the Pine Tree and Josephine mines. A 5-stamp mill for sampling was recently installed. This company's properties are all operated with electric power, the towns of Mariposa and Mount Bullion also being lighted thereby.

#### Placer County.

H. C. Armstrong will resume work at Canada Hill at the Golden West gravel mine in the spring. The tunnel is in 1300 feet and has struck the channel.

A Huntington mill and other machinery is being put in at the Buckeye, near Forest Hill.—At the Three Star-Almont mines, near Ophir, Superintendent B. F. Hartley is considering the advisability of doubling the mill capacity.—Ophir reports say that the Bouk has put in a 5-stamp mill.

#### Riverside County.

It is reported from Corona that the U. S. Tin M. Co. will put a copper plant on its Temescal tin mine holdings.

#### San Bernardino County.

At Daggett the Pacific Coast Borax Co. is doubling its capacity, and will again double the capacity during 1905. F. M. Smith is riding from Daggett to the Death Valley mines, and from there to Tonopah, following the proposed Tonopah tidewater railroad, which he is to construct. Surveyors are at work establishing the route. The proposed railroad will connect with the Salt Lake at Soda Lake.

#### San Luis Obispo County.

The Carissa Chemical Co. has been formed to exploit the borax deposits at Carissa lake, in eastern San Luis Obispo county, and ship the same to a refinery to be erected at Bakersfield, and has surveyed and staked 1500 acres of claims. A number of houses for the workmen have been built at the lake and two traction engines bought to haul the borax to Olig station, on the McKittrick branch of the Southern Pacific, whence it will be shipped to Bakersfield.

#### Shasta County.

G. Garwood of French Gulch was buried alive for nine hours on January 4th. Garwood and two mining partners, leasing the Pick-up mine, were in the French Gulch district running an upraise to connect one tunnel with another above. His pick struck an old fill and fine dirt rushed down, leaving him in a niche in the wall with barely room enough to turn around. His partners got twenty miners of the Washington mine to dig for nine hours, working in five-minute shifts—finally rescuing him uninjured, as enough air came from the old fill to keep him alive.

#### Sierra County.

At the Alaska mine at Pike City, in charge of G. St. John, the 450-foot vertical shaft will be retimbered and pumped dry. Machinery will be put in and run by electricity from the Colgate power house. A drain tunnel will be extended to tap the shaft and carry off the surface water.

#### Siskiyou County.

The late rains have caused a revival of hydraulic mining in Siskiyou county. The Minetta B. at Nulton is being worked with water from Thompson creek, a tributary of the Klamath, by T. J. Nulton, superintendent, and M. Gordon, foreman.—The Classic Hill, on the west branch of Indian creek, is being piped by J. C. Wood of Happy Camp.

#### Trinity County.

The 40 stamps at the Fairview mine, near Minersville, are run with power from Stuarts Fork. A contract has been let to run tunnel No. 4, which will strike the ledge 400 feet below tunnel No. 3, in which rich ore has been opened up. Tunnel No. 3 has been run in 1400 feet, in the face of the ledge.

#### Tuolumne County.

J. W. Burkitt of Arlington Heights, Ill., president of the Sierra G. M. Co., is expected to arrive in Groveland to start the mill and make improvements.

E. C. Loftus, manager of the Santa Ysabel, near Sonora, reports drifting going on on the 400 and 600 levels. The shaft is down 700 feet and will be sunk 1000 feet. The mill is being overhauled and put in shape.—Arrangements are being made to unwater the Belle mine at Tutletown.—The Mayflower mine is being developed by G. F. Bartlett.

At the Solsby mine water is increasing in the new works. It is thought that the water comes from the old claim.—The Black Oak mill is running with forty stamps, as all repairs on the mill have been completed.

It is expected that the forty stamps being added to

the mill of the Melones mine will be dropping in the spring, giving 100 stamps in all.

#### Ventura County.

The Columbia borax mine has been discovered in the Frazer mountains, 65 miles west of Lancaster. The company is planning to put a road through to Ventura. The borax is shipped from Lancaster to New Jersey, where it is refined. The ore lies in sheets between walls of clay and is shot down with giant powder and then sorted.

### COLORADO.

According to counties in 1904, Colorado produced:

County.	Gold.	Silver.	Copper.	Zinc.	Lead.	Total.
Adams.....	20,483	104,408	12,857	2,500	344	34,133,365

#### VALUE OF CONTENTS.

Gold, 17,645 ounces, at \$20.67.....	\$364,732
Silver, 1,391,461 ounces, at \$7.25 cents.....	796,611
Lead, 18,530 tons, at \$87.50 per ton.....	1,621,375
Copper, 147,562 pounds, at 12.5 cents.....	18,445
Total value for 1904.....	\$2,801,163

## REPORT OF ARGO SMELTER.

The Boston & Colorado S. Co. at Argo in 1904 produced:

Ore Supply.	Gold.	Silver.	Copper.	Total.
Colorado.....	\$1,347,218	\$245,296	\$101,556	\$1,694,071
Other States.....	134	2,018	100,064	102,217
Total.....	\$1,347,353	\$247,315	\$201,620	\$1,796,289
Gold, 65,184 ounces, at \$20.67.....	\$1,347,353			
Silver, 131,992 ounces, at 57.25 cents.....		247,315		
Copper, 1,612,961 pounds, at 12.5 cents.....			201,620	
Total value for year.....				\$1,796,289

The following is Colorado's mineral production for 1904:

Sources of Production.	Gold.	Silver.	Lead.	Copper.	Totals.
American Smelting & Refining Co. (Colorado plants).....	\$ 8,698,249	\$6,623,833	\$4,178,353	\$1,133,165	\$20,633,701
Ohio & Colorado S. & R. Co. (Salida).....	389,804	317,180	331,979	18,445	1,007,409
Boston & Colorado (Argo).....	1,347,218	245,296	101,556	101,556	1,694,071
Independent S. & R. (Golden).....	155,525	20,152	21,000	205,676	205,676
U. S. Mint, Denver (excluding shipments from Colorado plants).....	13,019,984	44,000			13,059,984
E. E. Burlingame & Co.....	472,261	12,000			484,261
Smelters and Refineries, Mints and Assay Offices, outside of Colorado.....	2,650,000	50,000			2,700,000
Estimated value of Zinc output.....					8,000,000
Clay and Miscellaneous Mineral Products, etc.....					21,000,000
Total.....					\$68,785,114

During 1904 the oil industry of Colorado has been in a prosperous condition, making an average production of 1800 barrels per day, 1700 barrels being produced in the oil fields at Florence and 100 around Boulder, or an annual total of 650,000 barrels of crude oil. There are 35 producing wells at Florence and 5 at Boulder, under the control of the United Oil Co., the entire product of both fields being refined at Florence.

## Boulder County.

The Eldora branch of the Colorado Northwestern road, running 33 miles, from Boulder to Eldora, has been completed in four months' time. Formerly the Boulder County mine and the tungsten properties have freighted ore by team 33 miles to Boulder at \$6 a ton. On the new railroad, ore can be shipped to Boulder for 50 cents a ton, and to Denver for \$1.75 a ton.

## Clear Creek County.

(Special Correspondence).—The Red Oak G. M. & M. Co., operating on Democrat mountain, near Georgetown, has let a contract to drive a 400-foot upraise from the Scepter tunnel to the Sunburst. With this opening they will be able to bring the ore down through Democrat mountain, instead of around as at present. During the winter months it is almost impossible to haul ore from the Sunburst on account of the heavy snow on the north side of the mountain. This company now has over 7000 feet of tunnel work on their property. They opened up a good body of high-grade silver ore a few days ago. Georgetown, Jan. 2.

The Chamberlain-Dillingham Ore Co. at Georgetown report having purchased 412,840 ounces silver, 888 ounces gold, 1,793,637 pounds lead; copper, \$2000; zinc, \$8000; shipped direct to smelters, \$75,000; total, \$419,342; This is an increase of over \$100,000 during 1904.

## Ouray County.

W. J. Hammond, Jr., manager of the Treasury T. Co. at Ouray, will add ten stamps to their new mill, making twenty in all. The electric power plant, run by 2700 gallons per minute of water from the tunnel, has been finished. The tunnel is in 5300 feet and seventy-five men are at work.

## San Juan County.

A. W. Harrison has charge of the survey for a tram line to connect the Grand Mogul with a mill to be built on Cement creek below Gladstone.

During 1904 San Juan county shipped 66,288 tons of ore and concentrates, as follows:

Silver Lake, concentrates, 18,600 tons, at \$48 per ton.....	\$ 892,800
Gold King, concentrates, 18,000 tons, at \$42 per ton.....	756,000
Sunnyside, concentrates, 5100 tons, at \$22 per ton.....	113,520
Silver Ledge, concentrates, zinc, lead and iron, 1978 tons, at \$27 per ton.....	53,406
North Star (Sultan mountain), crude, 1600 tons, at \$24 per ton.....	38,400
Shenandoah No. 3, crude, 750 tons, at \$65 per ton.....	48,750
Champion (Sultan mountain), crude, 318 tons, at \$38 per ton.....	10,494
Highland Mary, concentrates, 400 tons, at \$30 per ton.....	12,000
North Star (King Solomon mountain), Carson lease, 122 tons, \$3000; Kearns lease, 21 tons, \$3000; Dives, 48 tons, \$2000; Nicholson lease, 72 tons, \$2000; Benjosky lease, 96 tons, \$2000; Black Canyon, 48 tons, \$1400, and North Star Fraction, 96 tons, \$1000—total, 576 tons, crude.....	16,400
Amalgam and bullion from mills.....	571,000
Smaller producers.....	807,400
Total.....	\$3,320,170

Length of tram lines in feet are: Iowa G. M. & M. Co., 16,600; Sunnyside, 16,000; Silver Lake, 14,700; Silver Lake, Unity tunnel, 6000; Silver Lake, from Midway to mill, 2000; Gold King, 3300; Silver Ledge, 4000; Old Hundred, 4000; Royal M. Co., 1000; Thunder tunnel, 1500; Contention, 5300; Honrietta, 5460.

## San Miguel County.

The estimated mineral production of San Miguel county for 1904 is distributed as follows:

Tomboy Gold Mines Co.....	\$ 600,000
Smuggler-Union M. Co.....	500,000
Liberty Bell G. M. Co.....	400,000
Alta Mines Co.....	200,000
Nellie M. Co.....	150,000
Keystone Hydraulic Placer M. Co.....	50,000
Butterfly-Terrible G. M. Co.....	150,000
Opbir Con. M. Co.....	125,000
Yellow Mountain M. & M. Co.....	125,000
Suffolk Lode M. & M. Co.....	25,000
Carbonero mine.....	50,000
San Bernardino mine.....	20,000
Miscellaneous.....	105,000
Total.....	\$2,500,000

## Summit County.

The placers being worked near Breckenridge this season are the Revett gold dredging boat of the Reliance Gold Dredging Co. on French creek; the Summit Banner Placer M. & M. Co., L. Kingsbury manager; the Bemrose placers of Hoosier gulch by the Hoosier Creek M. & M. Co.; the Mekka Co., completing its 2100-foot drainage sluiceway; the American Gold Dredging Co. on the Swan river and Gold run, and the Gold Pan and Oro Grande in the Blue valley.

The Admiral G. M. Co., on lower Ten Mile, between Frisco and Wheeler, has run its crosscut tunnel 1500

feet.—The Copper Queen at Frisco is being developed by the Mary Verna Co. of Tennessee. An 800-foot crosscut tunnel is being run to tap the vein.—The capacity of the Quandy Mountain M. & M. Co.'s mill, operating on ore from the Monte Cristo, is to be doubled.—The new separation and concentration mill of the Old Union M. & M. Co. is almost completed. It will treat ore from the company's property on Mineral hill, and also custom ore.

A. E. Kaebles is manager and G. C. Smith superintendent of the mine on Mineral hill, near Breckenridge.

## Teller County.

The Merger G. M. Co. will reopen the Ruby mine, Bull hill, and the Bonnie Nell, Raven hill, Cripple Creek. W. J. Stark will manage both properties.

Taber & Sutton are putting in a hoist, hoiler and 6-drill compressor on the Helena of the Pilgrim Co.

During 1904 five cyanide plants were built near Cripple Creek: King & Craig on the Anaconda-Cripple Creek Homestake, which has the largest plant in the camp, and is now enlarging its capacity to treat 1000 tons daily; the R. E. A. & A., mining and cyaniding on the Wild Horse property; the Santa Rita, Gillett and Michorad. Russell & Rice will build a 1000-ton cyanide mill on Globe hill; C. B. Burch will build on the Little Giant property. The Lincoln of Cripple Creek cyanide plant is nearly completed.

## IDAHO.

State Mine Inspector R. N. Bell of Idaho has issued a statement showing the estimated metal production of last year to be as follows:

Gold, fine ounces.....	\$1,461.89
Silver, fine ounces.....	\$284,639.12
Lead, pounds.....	226,361,728.00
Copper, pounds.....	5,422,007.05

## Blaine County.

The tunnel being driven to tap the Red Elephant veins is in 900 feet, 600 feet remaining to be driven. The mill is running twelve hours a day, but will be run continuously when the tunnel is completed. An 80 H. P. boiler has been substituted for water power in running the mill and the compressor.

## Boise County.

C. M. Mullen is developing claims near Pearl.

## Custer County.

The White Knob Copper Co. is driving the main tunnel on its property near Mackay.

## Idaho County.

E. M. Aldrich is manager at Elk City of a New York company working on east fork of Crooked river, near Oro Grande. They may put in a 100-ton plant.—A 250-foot tunnel is being run on the Oro Grande group, 2 miles northeast of Elk City, under management of C. E. Svenson of Elk City. C. Brinton of Lewiston is owner.

## Lemhi County.

G. M. McKenney, manager of the Oregon-Idaho G. M. Co., operating the Singiser mine, near Salmon, says that the company has started up the mill and will open up the property during the winter.

## Owyhee County.

It is reported that an 8-foot vein of good bituminous coal has been found at a depth of 600 feet, near Bruneau.

## Shoshone County.

(Special Correspondence).—Owing to a disagreement involving right of way, the long lower tunnel recently projected by the Gold Hunter M. Co. of Mullan has been indefinitely postponed.

The Little Chief M. Co., through whose ground the tunnel must be driven to reach the Hunter vein, have asked such privileges for grant of right of way as the Hunter people are not disposed to concede. The tunnel, if driven, would do away with the tramway and bring the ore out to the mill.—The Hecla has declared an extra dividend of \$30,000 in commemoration of Christmas. This is in addition to the regular \$10,000 monthly distribution. The mine is at Burke, west of the Old Tiger-Poorman, the first mine discovered in the Canyon creek section of the Cœur d'Alenes.—The Stewart mine, on Stewart gulch, west of Wardner, is shipping a car of ore per month. The property appears to be the west extension of the Bunker Hill & Sullivan and the Last Chance lode. The ore now being extracted comes from tunnel No. 2. Tunnel No. 3, 250 feet vertically below No. 2, is being extended under the shoot now being worked in the tunnel above; it is expected to reach the objective point next month. H. F. Samuels, an owner in the Hercules mine at Burke, is the president and manager.—Supt. Fuller says that the Headlight Co. has a 5-foot face of concentrating ore on the foot wall side of the vein. The property adjoins the Mammoth mine on the west.—It is now proposed to start, in conjunction with Big Divide M. Co., a long tunnel from the canyon to the town of Black Bear. This will put the ores practically on the railroad and cut the vein at a farther depth of several hundred feet. The proposed new tunnel is estimated to be 2000 feet long when complete. An air compressor goes in. A McCullom, formerly foreman of the Standard mine at Mace, is the manager.—The various mining companies will pay into the treasury of Shoshone county this year the aggregate sum of \$99,119.24. Taxes are based upon net profits and improvements.

Wallace, Dec. 31.

At the Samson group on Big creek, near Wardner, the tunnel is in 100 feet. J. L. Safford is manager.

## Washington County.

The Ladd Metals Co. of Portland put in a smelter at

Landore last summer to treat the ores of the Seven Devils district and unsuccessfully experimented with a wood-gas converter for firing the stacks. The company has since rebuilt the smelting plant, enlarged its capacity and will now use coke for smelting.

The Iron Springs Con. M. Co., organized with office at Weiser, Idaho, and Eastern office at Youngstown, O., with a capital stock of \$5,000,000, purchased all of the properties owned by the Iron Springs M. Co., the Pacolian M. Co., the Holbrook M. Co., a controlling interest in the Iron Mountain M. & R. Co. and other properties near Iron Springs owned by individuals, on Rapid river and Bear creek. D. C. Nevin is president and manager at Weiser, Idaho; J. E. Stewart, first vice-president, Wooster, O.; H. G. Bye, second vice-president, Youngstown, O.; W. P. Barnum, secretary, Youngstown, O.; H. F. March, assistant secretary, Weiser, Idaho; J. F. Nevin, treasurer, Youngstown, O., and J. C. Sutherland, assistant treasurer, Weiser, Idaho. The company plans to put a 100-ton cyanide plant on the Iron Springs Co., will complete the wagon road from Iron Springs to Pollock and will put in an electric power plant on Rapid river. C. H. Dennison is superintendent at Iron Springs and J. B. Bye on surrounding properties.

## MICHIGAN.

(Special Correspondence).—The approximate production of the Lake Superior mines in 1904 was:

Mine.	Pounds.	Dividends.
Calumet & Hecla.....	79,000,000	\$4,000,000
Oscuela.....	20,500,000	192,300
Quincy.....	18,225,000	500,000
Tamarack.....	14,000,000	90,000
Champion.....	12,250,000	300,000
Baltic.....	11,900,000	
Trimountain.....	11,500,000	
Wolverine.....	9,850,000	450,000
Mohawk.....	8,400,000	
Atlantic.....	5,100,000	
Franklin.....	5,050,000	
Isle Royale.....	2,500,000	
Mass.....	2,450,000	
Michigan.....	2,400,000	
Phoenix.....	1,250,000	
Centennial.....	1,100,000	
Adventure.....	725,000	
Winona.....	550,000	
Ahmek.....	300,000	
Miscellaneous.....	50,000	
Total.....	206,900,000	

At present there are 16,000 men employed in copper mining on Lake Superior.

Beginning at the end of the Lake Superior belt: At the Phoenix work on the west vein has been abandoned and the St. Clair is being worked to partially feed the mill. The Ashbed may be opened to get enough rock. The Mohawk, one of whose shaft houses was burned, is in excellent condition. Its four producing shafts are almost equipped. Sinking on shaft No. 5 has been stopped. A shaft house is completed. South of the Mohawk the Ahmek has two shafts down and is shipping 160 tons daily from the extension of drift stopes. A second shaft is being started by the Allouez to tap the Kearsarge lode. The first will cut the bed in February. At the North and South Kearsarge mines and the Osceola branch the stamp mills have been improved and \$75,000 will be spent during 1905 to convert the heads. Wolverine is making the cheapest copper on Lake Superior, pays good dividends and maintains its production. At the Centennial production has been small, owing to the treatment of the surface accumulation. The Miskwabik and Bohemian range companies are exploring north of the Mohawk. The Mayflower and Old Colony companies are searching for paying lodes. At the Calumet & Hecla work has been resumed at No. 13 shaft on the Osceola amygdaloid. The stamp mills are being remodeled. Two shafts have been sunk in the Kearsarge lode and a third on the corner of the property for exploring. No. 19 is shipping rock regularly and No. 20 will begin in a short time. A power plant will be built at Lake Linden to supply electricity for the mines and mills.

At the Tamarack No. 2, shaft has been repaired and is producing copper.

On the Laurium two diamond drill borings have been completed and a third is now in progress.

The Tecumseh shows no signs of becoming active. The Rhode Island is exploring with indifferent results. The Franklin is in excellent shape and its new shaft at the Junior mine is penetrating good ground. The Quincy has made improvements in mine, mill and smelter. No. 8 shaft on the Mesnard property will probably be producing by the end of 1905.

At the Isle Royale a 150-foot shaft has been opened in Section 11.

The Atlantic has worked the more profitable stretches of ground. The Superior Copper Co. is down 90 feet. Baltic is operating normally. Trimountain is improving. Cbampan has ample drill capacity and is pushing development. It is enlarging its mill. Work on the Globe, owned by J. Stanton, may be resumed next spring. The St. Mary's Mineral Land Co. is sinking a drop shaft on its Challenge property, south of the Globe. The Elm River is exploring in No. 1 shaft. Wyandot is investigating a new hed uncovered in Misery river. Winona has discontinued production to develop its property.

Adventure's output has increased during the past six months. The Evergreen lode is being opened up. The Mass is developing shafts A, B and C. The Michigan is utilizing one head at the Mass mill and developing its ground. The Branch vein and Calico lode are doing well. The Victoria is doing surface work, as rock shipments can be made for five years without further development. A stamp mill is being built from the salvage of the Belt mill.

The Copper Crown M. Co. of St. Louis, Mo., is working the Hamilton.

Calumet, Jan. 1.

## MONTANA.

## Fergus County.

A 100-ton plant will be put up to treat ores from the mines at Kendall, owned by G. H. Stanton and H. Armstrong of Great Falls. Armstrong has charge at Kendall.

## Jefferson County.

The First Chance mine, above Deer Lodge, 4 miles from Basin, is owned and operated by J. C. Cope, A. S.

& W. Kilburn and W. Dodge, and has been developed by a 225-foot tunnel.

Madison County.

The Moonlight M. & Dev. Co. has been organized at Twin Bridges by D. F. Wheeler, president, and S. Thompson, secretary and treasurer.—The Groene-Campbell Con. G. M. Co. will build a 15-stamp mill on its property at Silver Star in the spring.

MISSOURI.

Jasper County.

The output of zinc in the Joplin district for 1904 was about 275,000 tons, valued at \$10,000,000. The lead output will aggregate 35,000 tons of ore, valued at almost \$2,000,000.

NEVADA.

Esmeralda County.

Manager Clark of the Bullfrog M. Co. at Amargosa states that the location work has been completed on the forty-five claims belonging to the company, and a 700-foot tunnel has been started to crosscut the ledge. Ore is being sacked from the shaft on the Ladd Mountain group, and a shipment will be made to test as to the best methods of reduction. The company is drawing plans for a milling plant. The surveys have been made for the pipe line.

E. A. Doran of Goldfield and Los Angeles, Cal., men will build a 25-ton stamp mill between Goldfield and Columbia.

J. E. Spiking will put in a 5-stamp mill on Ramsey street, Goldfield. It has been in use for five years 7 miles west of Lida.

Washoe County.

At Dogskin, 20 miles north of Reno, J. W. Solley, manager of the Salt Lake & Reno M. & M. Co., is working six men on their copper claims.

NEW MEXICO.

In reviewing the mineral production for 1904, the Santa Fe New Mexican says that the Director of the Mint reports the gold and silver production of New Mexico does not reach \$500,000, while there has been a loss in the production of copper, turquoise, iron and other minerals and metals. This decline in mining is offset by the great increase in the production of coal, which, during 1904, was almost 2,000,000 tons.

Socorro County.

It is reported that the leaching plant of the Dividend M. & M. Co. at Estey City will be moved to Alamogordo.

Grant County.

The Imperial M. & S. Co. has been formed to work properties at Shakespear, in the Lordsburg district. C. Yaeger of Lordsburg is New Mexico agent.

OREGON.

Josephine County.

C. B. Hanson, superintendent of the Opp mill, Jacksonville, says that the new 10-stamp mill is working satisfactorily. The amalgamators are F. Hale and J. H. Erskine. J. W. Opp of Jacksonville, J. F. Reddy and F. T. Perry are owners, and are contemplating putting in ten more stamps. Electric motors, with current from Gold Ray station, run the crusher, the stamps and the amalgamators.—The 10-stamp mill at the Lucky Queen on Jump-off-Joe, C. D. Crane of Grants Pass, manager, will be in operation in February. A turbine wheel, with water from Jump-off-Joe creek, having a 30-foot head, will run the mill during the winter months. The mine will be lighted by electricity.—At Fiddlers gulch J. H. Wittrock of Grants Pass is working the Pinal mine with an arrastra run by a 17-foot overshot wheel.—Piping has begun at the Booth & Dysert placer on Jump-off-Joe with three giants. J. Dyser is superintendent. H. W. Miller and C. T. Davidson of Jacksonville have leased the Howland & Cook placer mine on Forest creek. J. Davies has leased the Snauldinger placer mine on Forest creek and will operate it this winter.—E. H. Perkins of Wolf Creek, H. A. Perkins and A. C. Spence have leased for three years the Marshall placer mine on Coyote creek from W. Paine of Waldo. At the Gold Flat, reached from Reuben's siding, 3 miles of ditch is completed and 2 miles to finish. Operations will be commenced by end of January. Mr. Henley of Virginia City, Nev., is superintendent, A. W. Shearer, foreman.

UTAH.

Beaver County.

The Frisco Contact M. Co., D. P. Rohlfing, manager, ordered a 500-foot hoisting plant for the shaft on the extension of the Horn Silver vein.

The Majestic Co. of Milford, E. F. Freudenthal superintendent, is developing the O. K., Old Hickory and Harrington-Hickory mines with 100 men.

Juab County

The Uncle Sam mine at Tintic may put in an air compressor.

Tintic shipments for 1904 were:

Carloads	Carloads
Ajax.....117	Oshorne.....1
Anderson & Jensen.....1	Salvator.....25
Bullion-Beck.....318	Showers.....1
B. R. Smoot.....1	Star Con.....46

Summit County.

The Wabash M. Co. at Park City will order an air compressing plant of two units, each of a capacity of 22,000 to 25,000 cubic feet of air per minute.

During 1904 Summit county's biggest ore shippers were: Daly-West, 129,815,000 pounds; Silver King, 121,570,000; Ontario, 13,057,000; Kearns-Keith, 8,640,000; Woodside, 349,000; Crescent, 312,000; New York, 246,000; sundry, 2,696,000. Total, 276,665,000.

SOUTH DAKOTA.

Pennington County.

F. H. Long of Chicago, Ill., operating the Bullion mine at Keystone, expects to build a mill early in the spring.

WYOMING.

Wyoming during 1904 produced:

Coal, 1,820,533 tons, valued at.....	\$14,461,599
Gold.....	800,000
Copper, 7,000,000 pounds, valued at.....	1,050,000
Silver.....	50,000
Iron, 150,000 tons, valued at.....	250,000
Building stone, etc.....	100,000
Total.....	\$10,711,599

Coal statistics are:

Mine.	Tonnage.	No. of Men Employed.
Rock Springs, No. 1.....	331,119	542
Rock Springs, No. 7.....	270,229	328
Rock Springs, No. 8.....	301,276	328

All others (estimate).....	25,000	100
Totals for State.....	4,820,533	6,031

The Grand Encampment and Battle Lake districts were the chief copper producers. The greater part of the gold production came from the South Pass and Atlantic districts. Silver was not obtained except as a by-product.

Converse County.

The Douglas Oil Co., operating in Brenning basin, 12 miles from Douglas, have found a deposit of paraffine 3 feet in thickness, while drilling for oil.

FOREIGN.

BRITISH COLUMBIA.

Boundary District.

A compressor is being put in at the Betts & Hesperus group on Hardy mountain, 5 miles from Grand Forks, by Superintendent T. H. Rae.—At the Brooklyn & Stemwinder group, in Phoenix, Superintendent Collins will make a raise from the 250-foot level of the Brooklyn to the surface.—The Canadian Pacific, the Spokane Falls & Northern and the Kettle Valley Lines have issued joint ore rates from Ymir, B. C., and Chewelah, Wash., to Boundary smelters. The rate on \$15 ore from either point is \$1.75 per ton. The rate on \$10 ore from Ymir is \$1.50 per ton, and on \$25 ore \$2.50 per ton.—Ten blast furnaces in three Boundary smelters are now in operation—six at the Granby, two at the B. C. Copper and two at the Montreal & Boston. An underground telephone system has been put in the Granby mines.

Cariboo District.

(Special Correspondence).—The Slough Creek Ltd., developing the auriferous gravels in the Slough Creek region, has been placed in the hands of J. Gerdwood as receiver and manager. J. D. Kendall, employed by Glasgow people to examine the property, has reported favorably, stating that capital is necessary for development. A new company has been formed to continue the work.

Barkerville, Dec. 28.

Slocan District.

The Rossland Miner gives the following complete list of silver-lead mines in Kootenay that have paid dividends:

Payne.....	\$1,420,000	Noble Five.....	50,000.
Slocan Star.....	400,000	Goodenough.....	45,188
Idaho.....	100,000	Washington.....	38,000
Reco.....	287,500	Monitor.....	27,000
Rambler-Cariboo.....	220,000	Queen Bess.....	25,000
Last Chance.....	213,109	Jackson.....	20,000
Whitewater.....	208,000	Surprise.....	20,000
Ruth.....	125,000	Bosun.....	12,000
Sunset.....	68,000	Antoine.....	10,000
Total.....			\$4,763,297

The dispute between the Last Chance M. Co. and the Noble Five Co. has been settled out of court. The Noble Five is likely to start up in the spring, with W. H. Sandiford in charge.—Work has begun in the No. 2 tunnel of the Last Chance. Manager Pratt intends to resume operations in the upper workings.

CANADA.

Quebec.

Electricity has been substituted for steam at the Eustis mine at Capelton. The power house is on the Coaticook river, 1 mile above the Massawippi. Two 450 H. P. Crocker turbine wheels are supplied under 36 feet head with water from a 15-foot wooden dam 340 feet above the power house. The turbine shaft is direct connected to a 3-phase 200 K. W. Westinghouse generator supplying current at 2200 volts, 25 cycles, to motors for the air compressors, rock crusher and hoist. The 2-stage Rand class D-2, cross compound compressor belt is driven by a 100 H. P. Westinghouse, 2000 volt, constant speed, induction motor. The hoist is at the end of a 1000-foot

adit tunnel, through which power is carried by three No. 4 weather proof wires in a wooden box bolted to the rock wall of the tunnel. It has two cast iron drums, 72x48 inches, mounted on separate shafts and driven by a Westinghouse 150 H. P. 3-phase, 2000 volt, type F, variable speed induction motor, with a normal speed of 480 revolutions a minute. The total load hoisted is seven and one-half to eight tons. The shaft is 2000 feet on the incline. Starting the load with motor at rest requires 194 H. P. for twenty seconds to bring to full speed, but if the motor be started light and after fair speed is reached the load be picked up with the friction gear, the instantaneous starting current will be 96 H. P. for five seconds, 126 H. P. for ten seconds after starting with load on, and 107 H. P. to hoist at full speed. The main crushing plant has not been finished, but will be driven by 2000-volt motors. A 50 H. P. 200-volt slow speed induction motor drives a 20x6 crusher and rolls for temporary use.

MEXICO.

Michoacan.

(Special Correspondence).—E. B. Sanderson and J. M. Hillyer, with M. Morales as engineer, have denounced twelve pertenencias in the Arrio district, on the Los Pozos mineral belt, at the head of the placers in the Arroya Blanca and Rio de Chuta. The Los Pozos mineral belt can be traced from the Cerro del Agua, east of Tumbiscatio, to near the mouth of the Rio de Chuta, on the Pacific coast. The ground denounced consists of an immense iron blow-out occurring where a ledge of slate intersects the mineral belt at acute angles. The claim was worked extensively by the antiquas, the district taking the name Los Pozos (the holes) from the result of their operations. Near an antiqua cut a boulder was picked up recently, from which two assays run \$97,541.50 and \$75,445.50, respectively, carrying also a trace of cinabar. The values are found in stringers of white iron, which leads to pockets of granulated quartz and slate containing coarse free gold. Eight men are at work making cuts and stripping the ledge in antiqua style.—C. Ruiz has three arrastras at work grinding ore from his claim in the Arroya Honda, near Aguindo. Carrizal, Dec. 30.

Sonora.

(Special Correspondence).—M. P. Jacobson, proprietor of the Argano mine, near Nacozari, has received information that a 4-foot vein has been struck, assaying from 200 to 600 ounces of silver. The shaft has reached a depth of 125 feet.—Work on the Santo Domingo mine has been suspended and the pumps have been drawn temporarily. The Santo Domingo, in the Ajo mountains, 40 miles south of Cananea, is a silver-producing property. It is understood that the immediate cause of suspending work was the encountering of water in such quantities as to make further development operations very expensive.—A prospector claims to have discovered a valuable deposit of copper ore, with a trace of gold and silver, in a canyon northwest of Cananea, the erosion of the water having uncovered a vein 100 feet in depth and 600 feet long. Cananea, Dec. 30.

SOUTH AMERICA.

Chili.

Chili has two copper belts 100 miles apart, running north and south, largely through faulted sandstones upheaved by eruptive diorites. The principal developments have been made in the coastal belts, because of the greater ease of exploitation and transportation, the Cordilleran belt being very difficult of access. The accompanying information of mineral development is taken from a recent consular report. In the Checo district the Copiapo Co. has been working the Descubridora mine at Copiapo, Atacama, since 1825. In 1903 it produced 10,160 tons of 16% copper. The same company is working the Dulcinea, the Farellon and the Candelaria, in Puquitos district, and the San Francisco, Antonia and Carmen Alto in Ojancos district. W. T. Holberton is mine manager.

The Ojancos M. Co., under the control of Gibbs & Co., are interested in the Transito and Andacollo mines. The Tierra Amarilla and Bateas mines in Copiapo are worked by the Sociedad Industrial de Atacama, which own the Lautaro mine at Amolano in the San Antonio district. The chief gold mines outside the Inca district are the Jesus Maria, near Copiapo, and El Guanaco, near Taltal, though work at the latter is suspended owing to the change in the ores from gold to copper and to the flooding of the lower workings. Silver is worked in the Elisa mine at Bordes in the Sierra Amarilla. This mine supplies the State mint and produced last year 7339 kilos of bar silver from 10,011 tons of ore. The reduction works are at Pahellon and Tortoraillo, Freiberg barrel method being used. In the Taltal district, two silver mines owned by La Compania de Minas y Beneficiadora de Taltal, owners of El Guanaco mines, have been equipped with concentrating machinery to work low-grade ores. The cobalt mines of the district have been pinched out. Important borate fields are said to belong to the Borax Con., Ltd., to be held in view of future contingencies. Sulphur occurs in same district and is worked to supply material for the manufacture of gunpowder, used to blast the nitrate beds. Cobalt, borate of lime and sulphur occur in Copiapo. Sulphate of alumina is found near Yeso, in the Tierra Amarilla, in the department of Copiapo, which it is proposed to calcine at Pahellon and refine at Caldera. Large deposits of iron in the form of wide lodes exist throughout this department, the principal ores being hematite and magnetite of a very high percentage and remarkably free from foreign elements. They are not worked. Hitherto only those lodes carrying also a low percentage of copper have been mined, merely for use as a flux in the smelting of copper ores, and have been obtained principally from Patacones district, close to Copiapo.

La Sociedad Industrial de Atacama has a smelter in Tierra Amarilla which treated 17,526 tons of ore in 1903, also a branch at Caldera. La Compania Exploradora de Lota y Coronel smelter can output 5300 tons of refined copper a year. A copper smelter also exists at Tacna, in the north of the State. A Chilean company has a smelter

almost ready at Paihote, near Copiapo. Lixiviation is practiced by the Copiapo Co. at Puquios and there is a plant at Tortorillo which is being enlarged. At Taltal the reduction of high and low grade copper will shortly be undertaken. The smelting business is largely responsible for the increased quantity of coal required by the Republic, the 1903 imports at Taltal, Pisagua and Caleta Buena being: Australian, 92,092 tons; English, 62,937 tons; United States, 4325 tons. The equipment of both new and old mines and metallurgical works which is being extensively taken in hand has led to a large import of mining machinery, especially electrical drills.

## Personal.

W. B. TWITCHELL is superintendent of the Big Lead M. Co. at Ray, Ariz.

ROY U. BISHOP is now manager of the Greenback mine at Greenback, Or.

W. C. ALEXANDER is manager of the Black Diamond mine at Stockton, Utah.

M. G. EVANS is manager of the French Creek M. Co., near Breckenridge, Colo.

F. M. DRESCHER, M. E., has returned to Prescott, Ariz., from Denver, Colo.

R. A. PARKER has returned to Denver, Colo., from a professional visit to Mexico.

E. R. STAFFORD is superintendent of the Arizona Pacific Co. mines at Woolly, Ariz.

F. P. SWINDLER is superintendent of the Bamberger-De Lamar mines at De Lamar, Nev.

H. J. JESSOP is manager of the Cherokee Mexican Proprietary, San Julian, Chihuahua, Mex.

J. W. CARY of Cary & Fielding, Denver, Colo., is in New York City on business connected with his firm.

W. J. HAMMOND, JR., manager of the Treasury T. M. & R. Co., at Ouray, Colo., is visiting in Pittsburg, Pa.

P. C. MCCARTHY, manager Hidden Treasure mine, Lake City, Colo., has returned there from Denver, Colo.

C. MOREHOUSE is manager of the Nueva Australia, Porvenir and Soto mines at Guanacevi, Chihuahua, Mex.

C. RIVES has resigned as superintendent of the Pioche-Nevada M. Co., in Pioche, Nev., and is in Salt Lake City, Utah.

GEO. W. MAYNARD has been investigating a placer proposition at Greaterville, Ariz., and goes thence to Mexico.

R. D. HUNTER, manager Denver branch of the Sullivan Machinery Co., has returned to Denver, Colo., from Chicago.

R. D. SEYMOUR, manager Denver, Colo., branch Trenton Iron Co., has returned there from Salt Lake City, Utah.

A. L. WAYNE is manager of the Manhattan, 6 miles above the head of navigation on Mineral creek, near Coeur d'Alene, Idaho.

C. R. CLAGHORN has been appointed general manager of the coal properties of the N. W. Improvement Co. in Washington and Montana.

H. J. MEISEL, assayer and chemist, and W. T. Taylor, electrician, have resigned their positions with the Rawhide G. M. Co., Jamestown, Cal.

MANAGER R. L. EDWARDS of the Kittie Burton mines at Ulysses, Idaho, has gone to Houghton, Mich., to meet the stockholders of his company.

C. G. DENNIS is superintendent of the Rawhide mine, near Towle, Placer county, Cal. J. Stevens of Nevada City, Cal., has been made foreman.

HERBERT MARTIN of Stockholm, Sweden, is making a tour of the Western mining fields making examinations of large power plant applications.

JOHN H. MACKENZIE returned to San Francisco, Cal., from a professional visit to Nevada, a few days since, and is seriously ill with pneumonia.

R. EAMES, JR., mining engineer for La Fortuna M. Co., Mexico, and Associate Security Co. of New York, has returned to New York from the mines in Mexico.

J. A. CAMPBELL, treasurer of the Cananea Con. Copper Co., has returned from a visit to Los Angeles, Cal., where he has been recuperating from a spell of sickness.

ALGERNON DEL MAR is instructor in mine engineering and assaying at the Pacific Technical College of Oakland, Cal., and is also continuing his professional work.

CARY W. THOMPSON, who has been for six years manager of the Greenback mine at Greenback, Or., retires, and will make mine examination his specialty at Portland, Or.

N. D. PHELPS, formerly manager of the mining department of the Union Iron Works, San Francisco, Cal., has resigned to take the Spokane, Wash., agency of the Allis-Chalmers Co.

L. S. WOOD, for the past two years manager of the Ashanti Goldfields Corporation, Ltd., Obuassi, via Gold Coast Colony, West Africa, has resigned his position and returned to Denver, Colo.

M. K. RODGERS of the Daly Reduction Co. of Montana, and operating the Nickel Plate mines, Hedley, B. C., is now in Ashcroft, B. C., arranging for opening up the Maggie group of mineral claims on the Bonaparte river.

HORACE F. BROWN, E. M., has returned to San Francisco, Cal., from a visit of several months in Pittsburg,

Pa., where he has been conducting a series of experiments on the agglutination of dust from iron furnaces and ores, in his type of furnace, and reports the results highly satisfactory.

## Commercial Paragraphs.

DR. F. J. CRANE, 29 West Alameda Ave., Denver, Colo., is the owner of the Crane patent ore washer, now in use at Cripple Creek, Colo.

F. W. PERRY is now Western representative Niles-Bement-Pond Co. of 136-138 Liberty St., N. Y., with headquarters at 1711 Tremont St., Denver, Colo.

THE Vulcan Iron Works Co., Toledo, O., are sending out a handsome calendar for 1905, in color work, showing their steam shovels, operating under different conditions.

THE U. S. M. Co. have given the contract to equip the new Mammoth smelter, Shasta county, Cal., to the Westinghouse E. & L. Co. The Minneapolis S. & M. Co. have the contract for the structural work.

THE Cedar Hill Coal & Coke Co., with headquarters at Denver, have installed an Ottumwa box car loader at their Tobasco, Colo., mine. This mine is being equipped with up-to-date machinery, and promises to be a paying proposition.

THE Tallerdar Manufacturing Co. of Dolgeville, Cal., have produced a device for laying slip joint pipe without driving. It is claimed by the manufacturers that the pipe can thus be laid faster, and that it saves battering the ends of the pipe.

THE S. H. Supply Co., Denver, Colo., report sales of a 50-ton concentrating plant to Oregon; 100-ton concentrating plant using Bartlett tables to Old Mexico; 25-ton concentrating plant to Idaho Springs, Colo., and a 6-drill compressor and boilers to Montana.

THE Mine & Smelter Supply Co. of Denver, Colo., with branch houses in Salt Lake City, Utah, El Paso, Tex., and City of Mexico, Mexico, report the removal of their New York office from 139 Liberty St. to 42 Broadway. W. C. Hendrie is in charge of the New York office.

THE Chicago House Wrecking Co., W. Thirty-fifth and Iron Sts., Chicago, have made another big buy—this time no less than the buildings at the World's Fair, St. Louis. They will have an immense amount of good material to dispose of, and will doubtless share their bargain prices with their customers.

THE Rand Drill Co.'s agents in Colorado and other Western States, Cary & Fielding, 1711 Tremont St., Denver, Colo., report the sale of seventeen Rand compressors during the past six months. Cary & Fielding also represent the Power & Mining Machinery Co. of Cudahy, Wis., on their line of machinery.

H. H. WILLIAMS, formerly with the Brooklyn Rapid Transit Co., has been elected president of the Lake Shore Engine Works, Marquette, Mich. Mr. Williams is an experienced electrical engineer, and will push the manufacture of their electrically driven machinery in connection with their regular line of mining machinery.

THE Old Dominion C. M. & S. Co., Globe, Ariz., have placed with Borden & Selleck Co., Chicago, Ill., an order for forty-six hopper style Howe standard suspension scales and weigh baskets, also an order with the same company for two rubber belt conveyors. Borden & Selleck Co. are the general Western agents for the Howe Scale Co. of Rutland, Vt., also engineers and manufacturers of conveying and elevating machinery for every kind of material.

THE World's Fair judges awarded the F. W. Braun Co. of Los Angeles, Cal., gold medals for their exhibit of apparatus and appliances for assayers, metallurgists and chemists. Their exhibit was arranged in three groups, and F. W. Braun Co. advise that the highest award, a gold medal, was secured for each group. Among the medal winners were the following: Cary hydrocarbon burner, marvel crude oil burner, Braun gas burner, Cary furnaces, Braun cupel machine and Braun ore sampler.

COLORADO IRON WORKS Co. of Denver, Colo., report the following orders: Eight (100 cubic feet capacity) ore cars for the Cananea Con. Copper Co. in Mexico; six (17 feet diameter) Hendryx agitators for the Liberty Bell M. & M. Co. in Colorado; one set of 40x16-inch improved standard, wide faced, and two sets of 30x10-inch improved standard, narrow faced, fine crushing rolls for the El Cobre M. Co. in Cuba; also six single three-compartment Colorado Iron Works jigs for the same company; four Colorado Iron Works impact screens for the Cripple Creek-Homestake M. & L. Co., and a shipment of ore cars, etc., to the London M. Co., both in Colorado.

THE Allis-Chalmers Co. opened new sales offices in Philadelphia on January 1st in the Land Title Building. The offices heretofore maintained by the electrical department of the company, the Bullock Electric Manufacturing Co., in the North American Building, have been removed also to the Land Title Building, where they have been consolidated with those of the parent company. The new offices are under the charge of W. A. Wood. These interests include the power, electrical, pumping engine, hydraulic, saw mill machinery, flour mill machinery, and other departments which produce rock crushing machinery, cement making machinery, wood preserving machines and plants, mine hoists and machinery for mining and recovering gold, silver, copper and other metals.

## Dividends.

Bunker Hill & Sullivan M. & C. Co., dividend No. 87, \$75,000, payable Jan. 4; total paid to date, \$2,346,000.

## Books Received.

"Coal Deposits of Georgia," by S. W. McCallie, gives a logical account of the geology, topography and coal deposits in Walker, Chattooga and Dade counties. The illustrations are good, and, as a whole, the appearance of the book could well be studied by some of the other State geological surveys.

One traveling through the mining communities of our country cannot fail to be impressed with the great amount of disease prevalent wherever a number of persons are working together. Usually the region has been healthy before the introduction of artificial conditions by man, but coincident with his advent is great numbers is the entrance of sickness. This is due chiefly to ignorance and carelessness with regard to handling waste material. In the large cities the danger has been realized and is combated by regulations for municipal sanitation. The subject has been reduced to a practical science requiring intelligent study. The second edition of a "Handbook on Sanitation" by G. M. Price is a simple yet complete treatise written to define and regulate the dangers of overcrowding in cities. The subject is introduced by a brief review of principles, followed by a description of practical methods. The book is primarily of value to the sanitary inspector or candidate for that position, as it defines his duties, discusses the evils and gives extracts from Government laws and civil service examinations. But it is also of vital import to every manager interested in an efficient return from his employees, for sick men cannot do good work, and observance of simple precautions with regard to ventilation, water supply and sewage disposal will increase the productive capacity of any community. Practical information on these subjects and on heating and food supply is given in this book in a manner that can be presented only by a man of the ability and practical experience of Dr. Price. The book is published by John Wiley & Sons, 43 East 19th St., New York City, for \$1.50, or will be sent post paid by the MINING AND SCIENTIFIC PRESS on receipt of price.

The growing importance of mining as a science is shown when Caleb Pamely finds 1200 pages necessary for but a single branch of this subject in the fifth edition of "The Colliery Manager's Handbook." This is a comprehensive yet condensed treatise on the laying out and working of collieries. It gives emphatic corroboration of the dependence of mining upon the other engineering sciences, for in preparing himself for the ever-threatening unexpected, the mine manager must be acquainted with the rudiments of geology, chemistry and electrical engineering, the fundamentals of mechanical engineering and surveying, and practical mining in its entirety. For English practice the author gives a complete description. English methods are good, but they are conservative. In criticising the book, the reviewer will not dwell on the presentation, which is logical, so much as he will compare the English methods in contrast to the enterprising new world methods. Every English text on mining bears the unmistakable imprint of Callon. His methods were good, but they have been modified; and when the modern student sees the same illustrations in the latest books as in Callon's first text, he marvels at the lack of originality. The treatment of the subject is purely for British conditions. Much space is devoted to parliamentary acts governing mines in each of the shires. The chapter on geology deals with English occurrences only. The methods used in boring for coal are described in detail, but without reference to numerous labor-saving devices that are used in recent oil-boring practice. In comparing diamond-drill boring with other systems, he states that other methods will not keep the hole true and vertical, while diamond drilling will—a manifest misstatement. Methods of working coal mines are well illustrated by comparatively recent English practice. The chapter on shaft sinking gives a very complete description of special methods for sinking through quicksands by the Kind-Chaudron process, Poetsch freezing process, etc., but is woefully lacking in information about sinking in ordinary ground. Under the subject of surface arrangements, valuable information is given regarding the design and care of steam engines and boilers. Timbering is given but fourteen pages, mostly reproductions from the old classics. Examples of poor practice are recommended as all right; nothing is shown of square timbers. The chapter on mine drainage is very good. The mechanism of many standard types of pumps is ably described and well illustrated. The theory of ventilation is given in detail; practical examples do not receive commensurate attention. Rock and coal drills and coal-cutting machinery are well described in accordance with recent developments. The application of electricity and compressed air is described, but little attention is paid to its generation. The subject of safety lamps is given a detailed study. Despite minor defects, the book accomplishes its purpose. It also emphasizes the need for a similar treatise on metal mining. It is the typical text of the modern professor in mining and will be invaluable in its comprehensiveness as a reference text for colliery managers and students. It is published by D. Van Nostrand & Co., 23 Murray St., New York City, for \$10, and will be sent post paid by the MINING AND SCIENTIFIC PRESS upon receipt of price.

## Trade Treatises.

Of standard size (6x9 inches), and handsomely put up, Catalogue No. 6 from the Lake Shore Engine Works, Marquette, Mich., illustrates and describes their makes of mining machinery and hoisting engines.

## Latest Market Reports.

SAN FRANCISCO, January 6, 1905.

## METALS.

**SILVER.**—Per oz., Troy: London, 28 $\frac{3}{4}$ d (standard ounce, 925 fine); New York, bar silver, 61 $\frac{1}{2}$ c, refined (1000 fine); San Francisco, 61 $\frac{1}{2}$ c; Mexican dollars, 52c San Francisco, 48c New York.

It is said in Wall street that the recent advance in the market price of silver is due to the unusual demand—which exceeds the present supply. This demand is partially traceable to the war in the Orient and to the increasing trade of the United States with China, as well as a continued and very noticeable absorption of silver by India. As conditions now are, the consumer of bar silver must wait for the producer—a fortunate reversal of what has been the order of things for about fifteen years past.

**COPPER.**—New York: Standard, \$15.25; Lake, 1 to 3 casks, \$15.25@15.50; Electrolytic, 1 to 3 casks, \$15.25; Casting, 1 to 3 casks, \$14.87; San Francisco: \$16.00. Mill copper plates, \$17.00; bars, 18@24c. London: £68 15s spot per ton.

Copper has taken another upward turn and the best price for Lake is now \$15.50. The metal is somewhat higher in London, and if the present conditions prevail 16-cent copper would not be a surprise in the near future. The present quotation, \$15.50, is the highest since January, 1901, when it was 17 cents. Copper has seen many "ups and downs" during the past forty-five years. Within that period, the highest price was 55 cents, in July, 1864, and the lowest that year was 39 cents, in January. In 1873, the highest price was 35 cents and the lowest 21 cents. In January, 1880, the price was 25 cents. It has never reached this figure since, the next highest being 20 $\frac{1}{2}$  cents, in December, 1882, and January, 1883. In January, 1884, it had dropped to 18 $\frac{1}{2}$  cents, and this price has never been reached since. In 1896-97, the highest price was 12 cents, and in January, 1898, it went to 13 $\frac{1}{2}$  cents, and has never been so low since. The lowest price recorded in forty-five years was 9 cents, which was in June, 1894, a little over ten years ago, at which time many copper mines all over the world were closed, and some which continued to work were run at a loss. A study of the fluctuations of the copper market is interesting, as it forms, in a way, a historical record of industrial stagnation or activity; the attempts of large producers to corner the market, and various other manipulations, but it can be truthfully said that the great industry of copper mining has never been on a more firm or prosperous basis than at present, and the condition of the copper market, like that of iron, has become to be looked upon as a reliable index to our industrial activity.

**LEAD.**—New York, \$4.70; Salt Lake City, \$3.50; St. Louis, \$4.12; San Francisco, \$4.50, carload lots; 4 $\frac{1}{2}$ c 1000 to 4000 lbs.; pipe 6 $\frac{1}{2}$ , sheet 7, bar 5 $\frac{1}{2}$ c; pig, \$4.85. London: £13  $\frac{1}{2}$  long ton.

**SPELTER.**—New York, \$6.10; St. Louis, \$6.15; London, £24 17s 6d  $\frac{1}{2}$  ton; San Francisco, ton lots, 6 $\frac{1}{2}$ c; 100-lb. lots, 7c.

**TIN.**—New York, pig, \$29.00 @ 29.15; San Francisco, ton lots, 29c; 500 lbs., 29 $\frac{1}{2}$ c; 200 lbs., 30c; less, 31c; bar tin,  $\frac{1}{2}$  lb., 32 $\frac{1}{2}$ @ 35c. London, £132 spot.

**PLATINUM.**—San Francisco, crude, \$18.50  $\frac{1}{2}$  oz.; New York, ingot, \$19.00  $\frac{1}{2}$  Troy oz. Platinum ware, 75 @ 82c  $\frac{1}{2}$  gram.

**QUICKSILVER.**—New York, \$40.00 @ 41.00, large lots; London, £7 15s San Francisco, local, \$39.00  $\frac{1}{2}$  flask of 75 lbs.; Denver, \$45.00.

**BABBITT METAL.**—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6 $\frac{1}{2}$ c; extra, 17 $\frac{1}{2}$ c; genuine, 31 $\frac{1}{2}$ c; Eclipse, 35c.

**SOLDER.**—Half-and-half, 100-lb. lots, 19.50c; San Francisco, Plumbers', 100 lb. lots, 16.25c.

**ZINC.**—Metallic, chemically pure,  $\frac{1}{2}$  lb., 50c; dust,  $\frac{1}{2}$  lb., 10c; sulphate,  $\frac{1}{2}$  lb., .04c.

**NICKEL.**—New York, 40@47c  $\frac{1}{2}$  lb.; ton lots, 40@47c.

**ALUMINUM.**—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31@34c.

## STRUCTURAL MATERIALS.

**IRON.**—Pittsburg, Bessemer pig, \$16.35 @16.60; gray forgo, \$15.85; San Francisco, bar, 3c  $\frac{1}{2}$  lb., 3 $\frac{1}{2}$ c in small quantities.

**STEEL.**—Bessemer billets, Pittsburg, \$21.00; open hearth billets, \$21.00; San Francisco, bar, 7c to 12c  $\frac{1}{2}$  lb.

**WHITE LEAD.**—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6 $\frac{1}{2}$ c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails,  $\frac{1}{2}$ c  $\frac{1}{2}$  lb. above keg price; in 1 and 5-lb tin cans, 100 lbs. per case,  $\frac{1}{2}$ c. per lb. above keg price. Dry Lead—In bbls., 1 ton and over, 6 $\frac{1}{2}$ c; do. in kegs, 7c.

**LUMBER.**—(Retail): Pine, ordinary sizes, \$24.00@25.00; extra sizes higher; redwood, \$28.00@30.00; lath, 4 feet, \$4.50 @5.00; pickets, \$21.00; shingles, \$2.50 for No. 1 and \$2.25 for No. 2; shakes, \$13.50 for split and \$15.00 for sawed; rustic, \$28.00 @35.00.

**NAILS.**—This week the basic prices are: Wire, \$2.77; Cut, \$3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, \$3.35; Cut, \$3.55; 10d to 16d, Wire, \$3.45; Cut, \$3.35; 8d Wire, \$3.50; Cut, \$3.50; 6d and 7d, Wire, \$3.60; Cut, \$3.60; 4 and 5d, Wire, \$3.70; Cut, \$3.70; 3d, Wire, \$3.85; Cut, \$3.85; 2d, Wire, \$4.10; Cut, \$4.10. Special rates for carload lots.

**LIME.**—Santa Cruz, \$1.25 country, \$1.25 city  $\frac{1}{2}$  bbl.

**CEMENT.**—Imported, \$2.15@2.65  $\frac{1}{2}$  bbl.; California carload lots, \$2.10 f. o. h. at works; small lots, \$2.40  $\frac{1}{2}$  bbl. in sacks, 4 sacks to bbl., 10c for each sack returned.

## GENERAL SUPPLIES.

**ANTIMONY.**—New York, Cookson's, 7c; Hallett's, 6 $\frac{1}{2}$ c; San Francisco, 1000-lb. lots, 8c; 300@500-lb., 8 $\frac{1}{2}$ c; 100-lb. lots, 10 $\frac{1}{2}$ c.

**POWDER.**—F. o. b. San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15 $\frac{1}{2}$ c; less than one ton, 17 $\frac{1}{2}$ c. No. 1\*, 60%, carload lots, 13 $\frac{1}{2}$ c; less than one ton, 15 $\frac{1}{2}$ c. No. 1\*\* 50%, carload lots, 11 $\frac{1}{2}$ c; less than one ton, 13 $\frac{1}{2}$ c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9 $\frac{1}{2}$ c; less than one ton, 11 $\frac{1}{2}$ c. No. 2\*\* 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2.00 per keg. CAPS.—3x, \$5.50@6 per 1000; 4x, \$6.50 @7; 5x, \$8@8.50; Lion, \$9@9.50, in lots not less than 1000.

**FUSE.**—Triple tape, \$4.00 per 1000 feet, double tape, \$3.50; single tape, \$3.10; Hemp, \$2.75; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 feet and up.

**CANDLES.**—Granite 6s, 16 oz., 40s., 11c  $\frac{1}{2}$  set; 14 oz., 40s., 9 $\frac{1}{2}$ c.

**CHEMICALS.**—Cyanide of potassium, 98%-99%, jobbing, 23@24c  $\frac{1}{2}$  lb.; carloads, 23@23 $\frac{1}{2}$ c; in tins, 30c; soda ash, \$2.00  $\frac{1}{2}$  100 lbs.; hyposulphite of soda, 3@3 $\frac{1}{2}$ c per lb.; caustic soda, in drums, 3@3 $\frac{1}{2}$ c  $\frac{1}{2}$  lb.; Cal. s. soda, hbls., \$1.10@1.20  $\frac{1}{2}$  100 lbs.; sks., 90c@1.00; chlorate of potash, 12@13c; nitrate of potash, 6 $\frac{1}{2}$ @7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2 $\frac{1}{2}$ @2 $\frac{1}{2}$ c; powdered sulphur, 2 $\frac{1}{2}$ @2 $\frac{1}{2}$ c; flour sulphur, French, 2 $\frac{1}{2}$ @—c; alum, \$2.00@2.25; California refined, 1 $\frac{1}{2}$ @2c; sulphide of iron, 8c  $\frac{1}{2}$  lb.; copper sulphate, 5 $\frac{1}{2}$ @5 $\frac{1}{2}$ c; chloride of lime, spot, \$2.50@2.75; sulphuric acid, in carboys, 66% B, 1 $\frac{1}{2}$ @2c  $\frac{1}{2}$  lb.; nitric acid, carboys, 8c  $\frac{1}{2}$  lb.

**BORAX.**—Concentrated, 6@7c  $\frac{1}{2}$  lb.; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

**BONE ASH.**—Extra No. 1, 5@6c  $\frac{1}{2}$  lb., No. 1, 4@5c.

**RED LEAD.**—500 lbs. and over at one purchase,  $\frac{1}{2}$  lb., 7c; less than 500 lbs., 7 $\frac{1}{2}$ c. LITHARGE.—Pure, in 25-lb. bags, 8@9c  $\frac{1}{2}$  lb.

**MOLYBDENUM.**—Best, \$2.75  $\frac{1}{2}$  lb.

**CHROMIUM.**—90% and over,  $\frac{1}{2}$  lb., 80c.

**PHOSPHORUS.**—American,  $\frac{1}{2}$  lb., 70c.

**SILVER.**—Chloride,  $\frac{1}{2}$  oz., 90c@1.00; nitrate, 55c.

**MAGNESIUM.**—Pure, N. Y., 60c.

**MANGANESE.**— $\frac{1}{2}$  lb., \$2.75.

**SODIUM.**—Metal,  $\frac{1}{2}$  lb., 50c.

**BISMUTH.**—Suhnitrate,  $\frac{1}{2}$  lb., \$2.10.

**URANIUM.**—Oxide,  $\frac{1}{2}$  lb., \$3.50.

**MERCURY.**—Bichloride,  $\frac{1}{2}$  lb., 77c.

**FIRE BRICK.**—Domestic, carloads per 1000, f. o. h., factory square, \$25.00; soap and split, \$22.50; arch and wedge, \$27.50; skewback, \$30.00; circle, \$32.00.

**FIRE CLAY.**—Domestic, per ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. h., factory, \$8.50.

## New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING DECEMBER 27, 1904.  
778,817.—PICTURE EXHIBITOR—I. Anderson, Prescott, Ariz.  
778,818.—GOLD SAVING APPARATUS—I. Anderson, Prescott, Ariz.  
778,210.—CLOSED END TUBES—Anderson & Argall, San Jose, Cal.  
778,628.—BATH HOUSE—J. C. & E. H. Booker, Pasadena, Cal.  
778,301.—BIN—M. S. Burdick, Alameda, Cal.  
778,413.—OIL BURNER—C. F. Capell, Los Angeles, Cal.  
778,633.—PAY ROLL—C. T. Chichester, Placerville, Cal.  
778,741.—STAMP AFFIXER—J. P. & S. Farmer, Portland, Or.  
778,833.—DOOR SECURER—C. F. Fay, Seattle, Wash.  
778,234.—NOSE GUARD—W. D. Pennimore, S. F.  
778,777.—ANIMAL TRAP—J. W. Gates, Los Angeles, Cal.  
778,577.—OIL BURNER—J. L. Hague, Los Angeles, Cal.  
778,312.—SASH LOCK—W. L. Hall, Spokane, Wash.  
778,781.—FUEL—G. W. Herbelin, S. F.  
778,668.—PAPER ROLL PRINTING—G. D. Horton, Snohomish, Wash.  
778,666.—CONDUIT—A. J. Hoskins, S. F.  
778,682.—WHIP SOCKET—G. E. Kroning, Porterville, Cal.  
778,419.—SLIDE VALVE—H. C. Lenderman, Portland, Or.  
778,325.—IRRIGATING APPARATUS—J. H. Martin, Riverside, Cal.  
778,793.—TROLLEY WHEEL—E. J. McDonald, Los Angeles, Cal.  
778,790.—CALCULATOR—A. H. Merrill, Compton, Cal.  
778,762.—GARMENT PRESS—W. T. O'Brien, Portland, Or.  
778,547.—SEPARATING METALS—L. E. Porter, Camp Rochester, Cal.  
778,550.—ELEVATOR LOCK—R. J. Roulo, Los Angeles, Cal.  
778,551.—ELEVATOR LOCK—R. J. Roulo, Los Angeles, Cal.  
778,462.—PAPER FOLDER—A. E. Sexton, Los Angeles, Cal.  
778,468.—BOX NAILING MACHINE—D. Snitjer, Cupertino, Cal.  
778,813.—ROLL PAPER PRINTING—F. L. Taylor, Oakland, Cal.  
778,521.—PICTURE MATS—F. B. Wheat, Los Angeles, Cal.

## Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

ROLL PAPER PRINTING ATTACHMENT.—No. 778,813. Dec. 27, 1904. F. L. Taylor, Oakland, Cal., assigned to Acme Automatic Advertising Co., a corporation of California. The object of this invention is to provide a compact, simple, adjustable device which may be readily made to print or not, as desired. It consists of a roll paper printing attachment, comprising clamp members, arms pivotally connected therewith, said arms being bent intermediate of their ends and having a projecting part re-entering the angle included by so bending the arm, a printing roller journaled in said arms proximate to the angles thereof, an ink roller supported on said re-entrant portions of said arms and a distributing roller associated with said ink roller.

DEVICES FOR FORMING AND SIZING CLOSED END TUBES.—No. 778,210. Dec. 24, 1904. W. C. Anderson and F. L. Argall, San Jose, Cal. This invention relates to a machine, which is designed for the formation of hollow cylindrical bodies from disks of ductile metal, such as are especially required in the manufacture of tooth crowns, and for

**HENRY CAREY BAIRD & CO.,**  
Industrial Publishers, Booksellers and Importers,  
810 Walnut St., Philadelphia, Pa., U. S. A.  
Our New and Revised Catalogue of Practical and Scientific Books, 92 pages, 8vo.; a Catalogue of Books on Metallurgy, Mining, Prospecting, Mineralogy, Geology, Assaying, Analytic, etc.; a Catalogue of Books on Steam and the Steam Engine, Machinery, etc.; a Catalogue of Books on Sanitary Science, Gas Fitting, Plumbing, etc.; and our other Catalogues and Circulars, the whole covering every branch of Science applied to the Arts, sent free and free of postage to any one in any part of the world who will furnish his address.

One of the Greatest Technical Books in Any Language.

Langbein's Splendid Book on the Electro-Deposition of Metals.

FIFTH EDITION, REWRITTEN & ENLARGED.

PUBLISHED JANUARY 2, 1905.

PRICE \$4.00, FREE OF POSTAGE TO ANY ADDRESS IN THE WORLD.

## A COMPLETE TREATISE ON THE ELECTRO-DEPOSITION OF METALS

Comprising Electro-Plating and Galvanoplastic Operations, the Deposition of Metals by the Contact and Immersion Processes, the Coloring of Metals, the Methods of Grinding and Polishing, as well as Descriptions of the Voltaic Cells, Dynamo-Electric Machines, Thermo-piles, and of the Materials and Processes used in every Department of the Art. Translated from the Fifth German Edition of Dr. George Langbein, Proprietor of a Manufactory for Chemical Products, Machines, Apparatus and Utensils for Electro-Plating, and of an Electro-Plating Establishment in Leipzig. With Additions by William T. Brant, Editor of "The Technical Chemical Receipt Book." Fifth Edition, in great part Rewritten and much Enlarged. Illustrated by 170 engravings. In one volume, octavo, 694 pages.

Price \$4.00, free of postage to any address in the world; or by express, C. O. D., to any address in the United States, free of freight, \$4.00.

A circular of 8 pages quarto, giving the full Table of Contents of this splendid book, with specimens of the illustrations, will be sent free of postage to any one in any part of the world who will furnish us with his address.

810 Walnut St., Philadelphia, Pa., U. S. A.

## ROSE'S COMPLETE PRACTICAL MACHINIST.

The Complete Practical Machinist: Embracing Lathe Work, Vise Work, Drills and Drilling, Taps and Dies, Hardening and Tempering, The Making and Use of Tools, Tool Grinding, Marking out Work, Machine Tools, etc. By Joshua Rose, M. E. Illustrated by 385 engravings, 19th edition, greatly enlarged, with new and valuable matter. 12mo, 504 pages. Price, \$2.50. By mail, free of postage, to any address in the world.

By the same author:  
Rose.—Mechanical Drawing Self Taught, 350 illustrations. 8vo. .... \$1.00  
Rose.—The Slide Valve Practically Explained. Illustrated. 12mo. .... 1.00  
Rose.—Modern Steam Engines. Illustrated by 453 engravings. 4to. .... 6.00  
Rose.—Steam Boilers. A Practical Treatise on Boiler Construction and Examination. 73 illustrations. 8vo. .... 2.50

Elaborate Illustrated Circulars of the above Important Books will be mailed to any one in any part of the world sending his address.

The above books sent by mail, free of postage, at the publication prices to any address in the world.

**HENRY CAREY BAIRD & CO.,**  
Industrial Publishers, Booksellers and Importers,  
810 Walnut St., Philadelphia, Pa., U. S. A.

## WANTED.

BY TWO MINING MEN, LEASE ON PROPERTY containing mill with which the owners have not been successful. Address R.D.A., this office.

giving such tubes any desired size. The object of the invention is to provide an apparatus for the rapid shaping and sizing of metallic cylinders or tubes having one closed end from suitable disks of metal. This is effected by placing each disk upon a perforated die or surface and forcing them through by means of a corresponding plunger, then transferring the disk to another smaller die and plunger, and so on until it has been gradually shaped and given the desired diameter. In this invention an apparatus is provided by which this work can be rapidly done without delay to change from one die to another.

# GEO. E. WOODBURY,

## 223 First Street, San Francisco, Cal.

### AGENT FOR

# The Wilfley Concentrating Table

Simple in Its  
Construction.

Saves Fine  
Sulphurets.

Makes High  
Product.

Capacity from  
5 to 10 Stamps.

# RIDGWAY TWO-BELT CONVEYOR SYSTEM

A RADICAL DEPARTURE IN THE RIGHT DIRECTION.

**WEARS TWICE AS LONG. SAVES HALF THE POWER. OPERATES WITH HALF THE TENSION.**  
Belts lighter, more flexible, more lasting. Runs without flexing. Negotiates steeper angles. Power required to overcome rolling friction only. Renewal cost one-half. Minimum power, wear and tear. Self-lubricating and dustproof throughout.

BELT CARRIERS.

Outclasses Anything  
in the Market.

TROUGHING BELT.

**RIDGWAY BELT CONVEYOR CO.,**

29 Broadway, New York, U. S. A.

## Improved TALLERDAY Manufacturing Co.

DOLGEVILLE, LOS ANGELES COUNTY, CALIFORNIA.

**STEEL  
PIPE**

AND

**TANKS**

Tanks Shipped K. D.

THE TALLERDAY PATENTED STEEL ROLLING MACHINE rolls pipe from 4 inches diameter up to any required size, in 10-foot lengths, from 20-16-14 gauge steel. The advantages of pipe in 10-foot lengths instead of the ordinary 30-inch lengths are obvious—smooth interior increases carrying capacity and decreases friction. Less joints add strength and increase the life of the pipe. One seam in a 20-foot length instead of eight as in ordinary pipe. Use the improved Tallerday Pipe and you will never be satisfied with other makes. Write for Catalogue and Prices.

**SURFACED  
PROTECTED**

## PROTECT YOUR ROOF!

When you do, buy H&H Marble Faced Roofing. Never buy an unsurfaced roofing when you can get a surfaced roofing (H&H MARBLE FACED) at about the same price.

**H&H MARBLE FACED ROOFING**

won't wear out, crack or melt. **LIGHTEST—STRONGEST—BEST.** Not affected by vapors, steam or acid. Any workman can lay it. Requires no painting or patching. Samples and prices by mail.

## PIONEER ROLL PAPER CO.

Drilling Machines**Star Drilling Machine Company,  
Akron, Ohio.**MACHINERY FOR SALE.****FOR SALE.****SULLIVAN Diamond Core Drill.**

Has not been used long; in good condition; takes out a core 1½ inches in diameter; has 1000 ft. of drill rod, all in good condition. Is especially adapted for ores, stone and coal. Can be purchased cheap. With this machine you can tell what you have without spending a fortune in digging a tunnel or sinking a shaft. Address THE BLOOMFIELD MFG. CO., Bloomfield, Ind.

**FOR SALE CHEAP.****FILTER PRESS of Stilwell-Breece & Smith-Valle**  
Make, Having Been in Use Two Months.

This Press has 48-2" chambers. Together with this is a 7"x4"x10" DUPLEX PUMP. Can be seen by calling at the office of the undersigned. For further particulars, apply to CONFIDENCE G. M. &amp; M. CO., No. 320 Sansome St., Room 53, San Francisco, Cal.

**Dredger for Sale.**

A clam-shell dredger used only six weeks and in first-class condition. Hatch steel bucket, capacity 2 cubic yards level full; boiler 48 in. x 16 ft., return tubular; main engines are 12x18; spud engines are 8x12, solid bed plates; two large friction hoisting drums; three friction drums for handling spuds; machine set up with frictions, clutches, traveling spud, two main spuds, hoisting and spud chains, capstan, feed pump and every part complete in every detail and ready to run; weight of all iron work and machinery 4½ tons. Machine cost \$19,500; will be sold at less than 25% of cost price.

One 6-ft. new Pelton wheel, double nozzle, cost \$600, price \$125.

Three Woodbury Belt Concentrators, only used three weeks, price \$90 each.  
Address Box 16, Mining and Scientific Press, San Francisco, Cal.**WE GUARANTEE ALL OUR MINE AND MILL MACHINERY.**

This make of Engine is too well known to require any description. It is very heavy in construction and designed especially to withstand the most severe service. It is practically new, having had but about two months' service.

**SPECIFICATIONS:**

Style of Engine..... Right-hand.  
Size of Cylinder..... 12x14  
Rev. per Min..... 250  
Horse Power..... 70  
Band-wheel..... 60x15  
Weight about..... 6000

This is an Engine that will give the very best of satisfaction and longest term of service. It is practically new, and at the price we are ready to quote cannot help but interest prospective purchasers. Write at once.

Two of the FINEST. Flow is under control. Feed only as fast as consumed—NO WASTE. BRUNO, all iron. RENOWN, all brass. We make a variety. Send for booklet and make your selection. 427 Pacific Coast Jobbers. Address: The Wm. Powell Co., Cincinnati, Ohio.

**W. & P. ROOFING.**

Best wool felt, thoroughly saturated and coated; elastic, and unaffected by heat or cold; will not rust or drip like metal; unaffected by acid fumes or gases; is not inflammable like shingles. Good for mining plants, mills, factories, warehouses—any place where steam or vapors abound; for roofing and lining dry kilns—will stand heat and insulate perfectly; for dwellings, stables, barns, stock sheds, poultry houses—anything needing protection from sun and rain. Lowest in price; best, irrespective of price. If interested let us send you sample. **PACIFIC REFINING & ROOFING CO., 113 NEW MONTGOMERY ST., SAN FRANCISCO.**

**THE DIFFERENCE**

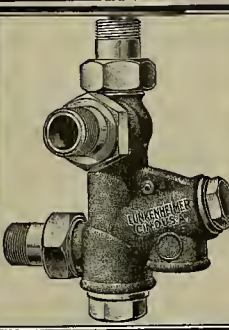

between Cars that are poorly constructed, which quickly break, and Cars that will stand hard usage, is not always noticeable when you first buy them. But Cars manufactured by us will stand hard usage. We use only the best materials and the most suitable construction.

We have everything else in

Assaying, Cyanide and Mill Processes Catalogue Free.

# THE GRIFFIN

## THREE ROLLER

# ORE MILL.

The Griffin Three Roller Ore Mill is a simply constructed Mill, suitable for working all kinds of ores that require uniformly fine crushing by the wet process. This Mill is a modification of the well-known Chilian Mill, but the rollers run upon a crushing ring or die, which is inclined inwardly at an angle of about 30 degrees, the rollers themselves also being inclined to the central shaft of the Mill, thus utilizing the centrifugal force, as well as the weight of the rollers themselves as a crushing agent. The Griffin Three Roller Ore Mill is therefore a Mill of great strength, and has few wearing parts. We construct these Mills with extreme care, using only the best of raw materials, which are most carefully worked by men who are specialists as mill builders. We sell the Griffin Ore Mill on its determined merits, and will gladly supply full information regarding it to any one.

## PELTON WATER WHEELS

### PELTON WHEELS IN COSTA RICA.

Cartago, originally the capitol of Costa Rica, Central America, was nearly destroyed by an earthquake in September, 1841. Although succeeded as a seat of commerce by San Jose, it is now rapidly recovering much of its lost supremacy. It enjoys an electric light company which has installed a Pelton Water Wheel of 300 H. P., operating under 250 feet head. By this means an ample supply of electric light and power is assured the inhabitants, and the regularity with which the Pelton Wheels work, running as they do for years without repairs of any kind, assures a permanency of light and power obtainable by no other means, so economical.

Our 88 page catalogue, which will be gladly mailed upon request, gives full details not only of the wheels we have installed, but also of the reliability and economical work which they are doing.

## MALLEABLE IRON WASHERS

One-third the weight of  
cast iron.

400 per cent stronger.

The engineers specify malleable instead of cast washers for the following reasons: They are lighter—A saving in weight of structure. They are thinner—A saving in length of bolts. They are stronger—No loss in breakage. They are perfect castings—No loss for defects. They permit a saving of 66% per cent of freight charges. **THEY ARE CHEAPER THAN CAST WASHERS.**

# SAMSON TURBINE

The illustration shows the large NIAGARA design, HORIZONTAL SHAFT TURBINES recently installed by us for the TELLU-  
RIDE POWER TRANSMISSION CO., power station, Logan, Utah. Tests conducted by competent engineers developed as follows:

Head.	Gateage.	Speed.	H. P.	Generator Eff'cy.	Turbine Eff'cy.
211.5 ft. .... 1-2	400 r. p. m. .... 1038	..... 95.20%	..... 73.80%		
209.7 ft. .... 3-4	400 r. p. m. .... 1560	..... 96.50%	..... 83.59%		
208.9 ft. .... Full	400 r. p. m. .... 1677	..... 96.70%	..... 80.57%		

These results have never been equaled by any turbine of the Horizontal Shaft Design, operating under equally HIGH HEADS. The test  
was made AFTER TURBINES WERE INSTALLED, direct coupled to Generators. Francis' weirs and formulae for discharge were  
used. The original test reports on file at our offices. These turbines are all fitted with our SAMSON BALANCED GATES. Note espe-  
cially the UNIFORM SPEED at ALL GATEAGES.

# PATENTS

DEWEY, STRONG & CO., San Francisco, Cal., and Washington, D. C.

We are prepared to transact business with our clients direct from either our San Francisco or our Washington office. We  
have representatives in every country in the world having patent laws. The information accumulated through long and care-  
ful practice before the Patent Office and the frequent examinations of patents already granted, for the purpose of determining  
the patentability of inventions submitted to us, enables us to advise inventors, often saving them the expense of applying  
for a patent upon inventions which are not new. All worthy inventions patented through us are described in the *Mining and  
Scientific Press*. Guide to inventors sent on application. Address

DEWEY, STRONG & CO., 330 Market St., San Francisco, Cal., or 918 F St., Washington, D. C.

# It's THE BEST

(and WE  
make them.)

The above picture shows one of our Traction Engine outfits in use in Nicaragua, C. A.; was used during late war by that Government for transportation of troops and supplies. Engine, 110 H. P.; car capacity, 16 tons each. Can be used on from 5 to 30 per cent grades, depending upon conditions of roads. Over 150 in use on this coast alone, and every one a money maker. Let us know the kind of freight you are hauling, per cent of the grades, usual conditions of roads, and we will tell you how to save 1/4 to 1/2 of your present cost of hauling.

Write for our new Catalogue No. 18, and we'll do the rest.

## SPADONE'S CONCENTRATOR BELTS.

PATENTED.

This illustration shows the edge flanging out-  
wardly as it passes over the pulley. This re-  
lieves the strain from the top and bottom of the  
edge by directing the strain automatically to  
the inside face surface of the edges. Hereto-  
fore all belts have been so constructed that  
when they pass over the pulleys or rolls, a di-  
rect strain comes upon the top or at the base of  
of the edges, causing the edges to break away  
from the body of the belts in a very short time.  
We avoid this Mechanical Defect by our Spadone  
Curved Edge Belts. Belts made to fit any machine—  
4, 5 and 6 feet wide. Prices and samples on ap-  
plication.

AMALGAM PLATE CLEANERS.

Our Amalgam Plate Cleaners are made of Pure  
Rubber in moulds, thus insuring a plate cleaner which will not  
scratch the plates and a perfect edge which will clean the  
Amalgam plates evenly. They are made 6 inches long, 3 inches wide and 1/4 inch thick, making a  
convenient size to handle. Price by mail to any address, each 75 cents. Correspondence solicited.

Send us your order for Water, Air Drill, Steam, Suction and Fire HOSE, RUBBER  
BELTING, RUBBER PACKING and LEATHER BELTING.

In the smoke clouded districts of the great cities P. & B. Roofing is the same success as in the mining and smelting districts.

Smoke and the elements have no effect on it.

It does not expand from heat or contract from cold; never leaks, rusts, curls or flakes off. It is just the kind of roofing you should use.

Booklet free.

## Paint

The best is always the cheapest. This rule particularly applies to paint. That is why P. & B. is the most economical for builders and contractors to use upon every description of iron work, wood work, stone or concrete. It positively preserves everything upon which it is used. Climate and the elements make no impression upon it and it is practically indestructible. All dealers sell P. & B.; therefore there is no excuse for accepting a substitute. For further details, write for our booklet; mailed free.

## Proposed Drainage of Cripple Creek District.

The leading mine owners and operators of the Cripple Creek, Colo., district are earnestly discussing the deep-level drainage tunnel, realizing that only by carrying out the proposed scheme can they hope to mine below the level of the El Paso tunnel. The district is fissured and broken and heavily saturated with water, and the futility of attempting to carry on mining operations below the present artificially created drainage level—the El Paso tunnel—without providing another similar adit at a lower altitude has been fully demonstrated. The cost of the El Paso tunnel was approximately \$35,000, and it is stated by leading mine operators of the district that this tunnel has already saved to the mine owners and operators more than \$500,000. In view of this fact, it is strange that there should be any opposition to the proposed new tunnel, though it is stated that one prominent mine refuses to join in the operation, claiming that this property was in no manner benefited by the El Paso tunnel, and that the proposed tunnel will be of no greater service. It is said to be a fact, however, that the water in the lowest level of the mine in question was lowered several feet by the drainage through the El Paso tunnel. The Mine Owners' Association will meet to-day, and it is hoped will be able to make some arrangement by means of which the work on the new tunnel may be started. In view of the slow progress of drainage of the large area which will ultimately be effected by the proposed tunnel, it is realized that an early beginning is necessary if there is to be no suspension of deep mining in the principal ore-bearing territory of the district. The cost of the El Paso adit, and its relative benefits, to this time, without giving consideration to the long-continued beneficial influence it must have until the drainage is effected by a deeper tunnel, it would seem, should be sufficient to determine every mine owner and operator in the district to do all possible toward the furtherance of so wise and profitable a plan as the construction of the proposed new drainage adit.

## Value of Expert Advice.

One of the much-discussed questions in the mining world is the value of expert and professional advice—presupposing that the advice is based upon sound and experienced judgment.

It is, perhaps, a difficult matter to place an arbitrary valuation upon the services of the advisory or consulting engineer; but for commissions of a limited time—a few days or a few weeks—it should scarcely be figured on a basis of time consumed. The knowledge of the mining engineer is a portion, at least, of his capital, and as such should earn him substantial recompense whenever he has opportunity to invest it. His knowledge has been gained by years of preparatory study and earnest practical application. If his services are sought, it is because his opinions are of value. If the valuation placed on this professional opinion or advice is to be measured by some other standard than that of time, as it properly should, let it be viewed in its relation to the money saved or made for the client. An engineer may be called upon to examine a mine which is without value from a commercial standpoint, and yet possess peculiar elements which readily deceive the inexperienced, who may be induced to invest a large sum of money in its development and equipment. The engineer reports adversely. Are his services of no value because he is unable to make a favorable report? Rather, as he has saved the would-be investors from a disastrous venture, should they be the more willing to pay a handsome fee. In such an instance the engineer is, perhaps, entitled to more than he would be were he able to give a favorable report, for in the latter instance the investors may have made a financial success without either his advice or assistance. There are many going mines operating successfully where the profits could be largely increased had the owners a competent advising engineer.

Often the mine development is not pursued on the best lines—the hoisting and transportation facilities are improperly arranged, and the reduction plant is disadvantageously placed or unsuited to the ore—all of which would be of value to the owners to know. For some reason, often when a proposed investment is discouraged by an engineer, the would-be investors feel somehow as though they would have been better satisfied had they not employed him, and they who are already involved do not always view an adverse report on their enterprise with favor, preferring to pursue the venture at a loss, but with a certain vain hope in their luck. "The laborer is worthy of his hire," and the consulting engineer is very often a most industrious and faithful laborer in the interest of his clients, and his services should be liberally and cheerfully rewarded.

## The Need of Foresight.

Mine superintendents sometimes get credit for being better managers than they actually are. In one instance it became necessary for a company to engage a new man to manage their gold mine, the superintendent in charge, for reasons of his own, desiring to leave. The new man on reaching the mine found things in good shape, a large amount of development work done, and everything in good condition for a prosperous year. He extended the development work, making more ore available, and proceeded to extract the reserves at low cost, and during the year produced a large net result. At the end of the year he resigned and was succeeded by another man, who thought he could do as well as his predecessor, but he neglected to advise the company promptly that the ore reserves were about exhausted. The proper thing would have been for him to close down the mill and proceed with development work as rapidly as possible. This, however, he did not do, but continued stoping and milling at the pace set during the previous year by his predecessor, while at the same time endeavoring to do development work in sufficient amount to increase, or at least keep up, the amount of ore in sight. In his eagerness to follow in the footsteps of the man before him he stoped the ore too close to the shaft and a cave resulted which nearly lost the shaft. At the expiration of his year of hardship and misfortune the second superintendent resigned and was succeeded by his predecessor, who had a sound excuse for clos-

ing down the mill and developing the mine until sufficient ore was in sight to keep the mill steadily employed when it did start up. Here is given an instance of a condition not infrequently seen in the management of a mine, and it exemplifies the necessity of operating a mine in such a manner that it may be capable of making a steady and profitable output, if it has the elements of success within it. Making a spurt in production one year, to be offset by an idle mill and expensive dead work the next, is not the best mining practice, yet it is the clever manipulation of this kind of opportunity that has sometimes made a reputation for success for the one and incompetency for the other.

## Montana's Proposed Mining Law.

Recently the Association of Mining Engineers of Montana, at their annual meeting, took up the question of needed amendments to the local mining laws, and some important suggestions as to Montana's needs in that direction were made. Among other things, it was proposed that the State Mine Inspector should be a graduate of a school of mines of recognized standing; that each of the mines of the State shall annually file with the State Mine Inspector complete maps of their underground workings, and that the stealing of ore should be made a criminal act, and not a mere matter of damages. The matter of drafting suitable bills and of further suggestions was given into the hands of a committee composed of some of the most distinguished engineers in Montana, and, without doubt, the matter will receive earnest and proper attention. In each of the Western mining States, there is no doubt of the need of legislation which would be to the advantage of the industry and to those engaged in it. The business of mining, however, has in many instances, perhaps unfortunately, become so closely identified with stock speculation, that the conduct of mining affairs is often influenced by other considerations than those which are best for the industry at large. There is no doubt that a law, making the stealing or intentional misappropriation of ore a crime punishable with imprisonment, would have a greater effect upon those who are disposed to do so than the mere assessment of monetary damages, but the placing on file of a complete map of underground workings, presumably for public inspection, is such a radical departure from the customary practice that it is extremely doubtful if such a bill can ever become a law in Montana or any other western State. It is interesting to contemplate the placing of such a map in the office of a State officer, where it may be seen by the public the same as other public documents and maps, by a corporation whose annual reports show clearly to how small an extent the stockholders and the public are taken into their confidence. However, it is wholly proper that the societies of mining engineers in the several States should take up and endeavor to bring about legislation which shall prove of benefit to the industry which they represent, and there is certainly abundant opportunity for the exercise of this prerogative.

DURING the summer of 1904, by joint arrangement, several Atlantic States universities leased and worked a mine in Colorado for the express purpose of giving mining students the desired opportunity to do practical work in mining, which is difficult to get in the East. It is along this line that the students of the Colorado School of Mines a few days since took complete charge for a time of the works of an ore testing company at Denver and operated the plant for several days, having an opportunity of going into every detail of ore sampling and testing. As an outcome of the latter experience, it has been determined to equip the Colorado State School at Boulder with a complete sampling and testing plant. Universities and mining schools generally have complete laboratories and small metallurgical plants; but few, if any, of them are equipped upon anything approaching a commercial scale. It does not appear absolutely necessary that such plants be of so extensive design, but the students undoubtedly get a broader idea of his work from an opportunity to see a commercial plant in operation, and is still further benefited if permitted to aid in the work himself.

## CONCENTRATES.

NO. 2 COPPER WIRE is 0.258 inch diameter and weighs 1059 pounds per mile. No. 2 aluminum wire weighs 319 pounds per mile.

THE platinum found in the Grand Encampment district of Wyoming occurs in the copper mineral covellite, a copper sulphide, of rare occurrence.

THIN strips of tin, brass, copper and steel make good shims and should be kept at a convenient place in the engine room of hoist or mill. They are worth a good deal when needed.

CHROMIUM is found usually in combination with iron, and occurs almost exclusively in dark, basic rocks, notably in serpentinite. The chrome-bearing rocks are high in magnesia and low in silica.

MANGANESE is present in nearly all rocks, usually occurring in small fractions of 1%. It is due to the fact, probably, that manganese is frequently found in the superficial exposures of many rocks.

THE tripod is used to some extent in underground work in setting up machine drills, but far less extensively than bars. The use of the tripod seems to be restricted almost wholly to certain districts.

THE limitations of electric power transmission, either as to voltage or distance, have not been reached. What in time these limitations may prove to be can not be even surmised, it being mainly a question of commercial possibility.

SALTPETER is sodium nitrate ( $\text{NaNO}_3$ ). It is this natural salt that is mined in large quantities in southern Peru. It is very similar to potassium nitrate, but is less valuable than the latter. It is employed in the manufacture of nitric acid and in making refined saltpeter.

BARIUM not infrequently occurs in igneous rocks, particularly in rocks high in potash. It is found as a constituent of orthoclase. This fact is probably responsible for the occurrence of heavy spar as the gangue of some veins in orthoclase-bearing rocks, as, for instance, the rhyolites of Calico district, Cal.

IT will probably result in broken cams to give the stamps 113 drops per minute on even a 5-inch drop, as the wear of the shoe and die increases the height of drop, when the falling tappet will strike the cam. It is not usual to give stamps over 110 drops, and generally they do not exceed 100 drops per minute.

THE hyposulphite of soda is employed in leaching the natural chloride ores of silver, as well as those which have been chloridized artificially. Often the extraction of the silver from the ore is much more easy of accomplishment than the subsequent treatment of the silver sulphide precipitate obtained in the process.

IN the construction of a dam it is important to provide means to prevent the water washing out a breach in the top of the dam should the structure be submerged, and also to guard against the water so passing over undermining the base of the dam on the lower or down-stream side. Neglect to look to these matters has resulted in the loss of several dams.

IN making concrete, the material used must be good—clean, firm rock, broken to proper size and screened to remove the fines, dirt and dust, clean, sharp sand and first-class cement. The proportions vary somewhat, from two to four parts sand, and four to ten parts rock to one part of cement. These proportions vary according to the character of the work.

WHAT is known as the Russell process is the treatment of roasted silver ore with a solution of cuprous sulphite:  $2\frac{1}{2}$  parts  $\text{Na}_2\text{S}_2\text{O}_3 + 5\text{H}_2\text{O}$  and 1 part  $\text{CuSO}_4 + 5\text{H}_2\text{O}$ . Silver, silver sulphide and the antimonial and arsenical silver minerals (ruby silver) are soluble in this solution, whereas none of them with the exception of silver are soluble in the hyposulphite of soda solution alone.

BABBITT METAL is generally made of tin 96 parts, antimony 8 parts and copper 4 parts. The idea of the use of babbitt metal in bearings is to use a soft metal which will conform to the shaft revolving in it. Isaac Babbitt, who invented and patented this method of lining journal bearings, did not take out a patent on the alloy. He used an alloy somewhat softer than the babbitt of to-day.

IN securing a hoisting rope to a bucket, skip or cage, it is better to pass the rope around a thimble of proper size, and turn the end of the rope back, securing it by means of three or four stout malleable iron clips, carefully placed. Leaded sockets are sometimes used. Through the thimble pass a safety hook of some good design, which permits the skip or bucket to be quickly removed in case of necessity.

THE Rand was first proclaimed as a gold field in September, 1886. The first milling operations were commenced in the spring of 1887. During that year the output was a little over \$460,000. It rose steadily, reaching \$24,000,000 in 1891, and nearly \$86,000,000 in 1898. The first nine months of 1899 the output was nearly \$80,000,000. The war then began, and production nearly ceased until the close of the war.

IF Portland cement clinker be ground just as it comes from the coolers, without the addition of any retarding substance, the cement will set too quickly to allow of its being properly worked; but if 2% or 3% of gypsum be added to the clinker and ground with it, it will retard the rapid-setting tendency of the cement. In some cases finely ground plaster of Paris is added to the cement after grinding, for the same purpose.

A PIPE LINE when exposed on the surface, whether for conveying water, air, oil or other substance, should be provided with slip joints in a country where there is a wide range of temperature. Neglect to provide these necessary devices may result in the breakage of the line. Air lines are more subject to expansion than lines carrying liquids. Pipe lines laid on steep hillsides should be carefully anchored with iron rods, ropes or chains.

FLAT ROPES are considered by many as superior to round ropes for hoisting, but they are not commonly used to greater depths than 2500 feet. A flat rope has the advantage of having the strands in sight, and greatly increases the opportunities for detecting broken wires or other defects. At some mines it is the weekly practice to thoroughly clean and inspect the ropes, which decreases the likelihood of accidents due to breaking of the rope.

THE Archæan rocks are the oldest known rocks, and antedate the Algonkian. The Archæan is divided into two prominent divisions—Laurentian, the older, and Huronian, the younger period. No distinct organic remains are found in either of these formations. The Algonkian is intermediate of Archæan and Cambrian, is of local occurrence, and is usually difficult of identification where no non-conformity exists with an older formation.

THE average value of manganese produced in the United States in 1903 was about \$8 per ton of 2000 pounds, the price varying with the market for the several States. In California it was about \$11 per ton and in Georgia about \$6. The value of the several varieties of manganese ores, that is, iron-manganese ores, zinc-bearing manganese, etc., varies in the several States the same as for pyrolusite or psilomelane, the most common ores of manganese oxide.

A MINING CLAIM located January 1, 1904, is not subject to relocation until midnight December 31, 1905, if no assessment work has been done up to that time, unless a State or local law requires a stated amount of work as a part of the act of location. The same applies to a claim located any day during 1904. For instance, a claim located December 31, 1904, would require assessment work in 1905, which if not performed within that year would subject the claim to relocation the first day of January, 1906.

SILVER may be extracted from matte by the Augustin process, in which the matte is roasted with salt, forming the silver present into chloride, which may then be leached out by means of hot salt solution, the silver being precipitated on metallic copper. By what is known as the Ziervogel process silver may be recovered from silver-bearing copper mattes by roasting the matte and washing out the silver with hot water in the form of silver sulphate. In this process, like the other, the silver is precipitated on metallic copper.

MANY zones of micaceous schist carry gold, and are generally very free to amalgamate, but when graphitic is present in considerable amount—not an uncommon occurrence—the ore is difficult to treat, owing to the "sickening" effect of the graphite on the globules of mercury. If the ores are stamped and run to settling tanks a great deal of the graphite will float away on the surface of the water, when the pulp may be run through a regrinding mill of some description and amalgamation accomplished without much difficulty.

IT is customary to figure 13 cubic feet for one ton of solid quartz rock in place and 20 cubic feet for one ton of broken rock. This varies somewhat with the character of the ore. Sometimes, particularly in the upper portion of ore deposits, the original ore has been leached, leaving many porous places and vugs. Such rock as this would require more than 13 feet per ton. Ores heavy in iron oxide require somewhat less. Sulphide ores of course require less, the amount being determined by the quantity of sulphide present and its specific gravity.

THE difference in statements as to the amount of broken rock shovellers could handle in a shift's work probably represents the difference in the nature of the material handled. Some kinds of rock break small and are much more easily shoveled than others. The personal equation is also a large one. Some men who can shovel more muck on a shift than any of their companions may not be fitted to do any more skilled work. A man may be an excellent miner and break rock with ex-

cellent judgment, and still not be able to hold his own with a crew of experienced muckers. In some mines the machine men do little or no mucking; in others the machine crew handles their own dirt.

TALC is of several varieties, foliated, occurring in leaves or folia easily separated. It is white, or greenish-white, in color, greasy to the touch and free from impurities. Massive talc, or steatite—also called soapstone—is coarse-grained and of various colors—gray, greenish, roddish, cream colored, etc.—due to the presence of iron oxide and other impurities. It is a very common mineral. In composition it is very close to serpentine, but the latter contains a large amount of water. Talc contains: Silica, 63.5%; magnesia, 31.7%; water, 4.8%. Serpentine has the composition: Silica, 44.1%; manganese, 43%; water, 12.9%. The water is expelled from serpentine at a red heat; from talc only at a high heat.

GOLD, as well as silver, is of frequent occurrence in limestone; in some cases the gold occurs without other mineral, as at the Alvord mine, 23 miles northeast of Daggett, San Bernardino county, Cal., where gold is found in a perfectly white marble, though at no great distance from a body of gold-bearing iron ore. At Oro Grande, Cal., gold was found in pure calcium carbonate in the Carbonate mine, and a similar occurrence was noted at the Marble Point mine, on the main fork of Tuolumne river, near Groveland, Cal. Gold is also distributed through a large mass of crushed limestone in the Black Hawk mountains, in San Bernardino county, Cal., and 5 miles to the northward gold and silver are found in limestone on a mesa known as Silver Reef.

SMALL AUXILIARY HOISTS may be operated at underground stations for sinking winzes, shafts, etc., and may be driven by electricity, steam or compressed air. Steam is objectionable, as it heats the mine workings, and the exhaust has a deteriorating effect on the timbers. There is also a great loss by condensation. As at most mines there is a compressed air plant, air would probably be the most satisfactory, as involving little additional expense. A small hoist which has been used on the surface for prospecting would be suitable for underground use. If it is to be frequently shifted a smaller hoist is preferable to a larger one. Shafts are frequently sunk below the lowest working level by means of auxiliary engines, a bulkhead being placed over a portion of the shaft for safety of men below.

WHEN A's claim crosses B's claim, the latter being the senior location, the right of A to follow his lode or vein across B's location to reach the farther end of his (A's) claim is a question upon which the courts do not fully agree. In Colorado and Montana the junior cross lode claimant (in this case A) has a right to drift through the older claim, following the cross vein, but giving the ore mined to the owner of the senior location. In California and Arizona this right is denied. The matter has never been passed upon by the Supreme Court of the United States, and until such time as it is settled by that court each State will have to settle disputes of this character in accordance with the ideas of the several State courts. The senior locator, however, is owner of all the veins within his claim, whether the outcrop at the surface were previously known or not.

THE cost of tunneling varies greatly, dependent upon the character of material passed through, the amount of timbering necessary, size of cutting and cost and efficiency of labor. It often costs more to complete a tunnel through soft rock than through that which is hard—in some cases the former is double that of the latter. Hard rock though more expensive to break stands well without support, whereas soft rock requires the most substantial kind of timbering and often frequent renewals, where caves occur. This refers more particularly to large than to small tunnels, though tunnels driven for drainage or transportation in mines share to a great extent the same conditions. The cost of driving a tunnel 5x7 feet through hard rock with machine drills is about \$6 to \$7 per foot where wages are \$3 per day. This varies with the manner in which the ground breaks—short or large.

By "rusty gold" is meant gold which is covered by a film of some mineral substance which renders the particles or grains difficult or impossible of amalgamation. It may be that a coating of this description might be impervious to cyanide or other solutions. The substances which coat gold in the manner referred to are iron oxide, manganese oxide and silica. The best way to treat gold thus coated is probably by attrition in a grinding mill of some kind. This brightens the gold and it should then be amenable to some process by which it may be collected and recovered. By mechanical means gold, which is bright and prompt to amalgamate, may be coated with silica so as to resist the attack of mercury. This has been done experimentally by placing nuggets of gold in finely pulverized quartz and subjecting it to heavy pressure. The fine sharp grains of quartz penetrate the outer surface of the gold and firmly adhere to it, completely preventing the contact of the metal with mercury, although the gold may look clean and bright, owing to the transparency and microscopic size of the particles of silica. As suggested above, these may be removed by attrition, though not so well by stamping.

## The Porcupine Placer District, Alaska.\*

Written by CHARLES W. WRIGHT.

The Porcupine gold field, one of the most important placer districts of southeastern Alaska, lies in a rugged mountain belt drained by the Chilkat, a river emptying into Lyun canal. The district embraces an area of about 100 square miles, its central point being approximately in latitude 58° and longitude 136°.

Placer gold was discovered in Porcupine creek in 1893, and developments begun during the following year have continued to the present, with a rapid increase in the output of gold, which aggregates about \$460,000. These placers lie close to the international boundary, and their extensive development has in a measure been dependent on the final settlement of its location.

In 1899 the Geological Survey dispatched an expedition to explore the northern front of the St. Elias range and the headwaters of White and Tanana rivers. This party, under the leadership of W. J. Peters, made its way inland by the Dalton trail, passing close to the then newly discovered gold placers of Porcupine, thus enabling A. H. Brooks, who was attached to the party as geologist, to make a cursory examination of a few of the claims on Porcupine creek.

The growing importance of this district led to a demand for a more systematic examination, and to this investigation the writer was assigned.

**DISCOVERY.**—Placer mining in the Porcupine district dates from the summer of 1898, when locations

expected on Glacier creek, though this has not been sufficiently prospected to determine the local distribution. The gravels of the tributaries entering Klehini river from the north are believed to be of no economic importance.

**CLASSIFICATION OF PLACERS.**—There are three types of gravel deposits in the Porcupine basin—creek gravels, side benches and high benches. The creek gravels fill the present channel to various depths and can not be definitely separated from the side benches or gravel banks which rise in places 20 and 30 feet above the stream. The high gravels occupy portions of former channels, which in some places have been preserved and in others have been cut out by the downward erosion of the streams.

The first of these side bench deposits, at No. 2 below Discovery, is an extensive gravel bed on the east side, 25 feet above the creek. Rich gravels occur at high benches, 80 feet above the creek, on the first three claims above Discovery, and a similar deposit has been found on the south bank of McKinley creek,  $\frac{1}{4}$  mile from its mouth, at an elevation of 200 feet.

**CHARACTER OF GRAVEL.**—The stream and bench gravels consist mainly of a fine wash containing worn slabs and fragments of slate and rounded boulders, often 2 and 3 feet in diameter, mostly of diorite, with some greenstone. In the upper portions of the creeks the gravel wash becomes coarser and more angular. There are no materials in the gravels

progress had been made toward consolidation up to the close of the season of 1903.

**GROUND SLUICING.**—As the best pay dirt is usually at the bottom of the creeks, it is necessary to remove the overlying gravel wash by some economical method. The stream must first be diverted into a flume built up on trestle work or running on one side of the creek. The creek bottom being freed from water, the large boulders are piled along the banks of the stream—those too heavy to move being broken by sledge hammers and powder. A narrow channel built up of boulders is thus formed, which serves to confine the stream and increase its velocity, so that on being turned back into the creek bed it is able to carry off material which it could not otherwise have moved. The miners often enter this swift-flowing stream and, by the use of shovels, help the larger rocks down stream and off the claim. From time to time the water is diverted into the flume, so that the large boulders may be thrown out or broken up. Where the creek bed is wide this temporary channel, continually eating its way downward, must be moved, step by step, from one side of the creek to the other, then perhaps back again in case the gravels are deep. In this way the mass of gravel is disintegrated and washed away and the gold is concentrated in a shallow deposit on bedrock. To clean up the bedrock, sluices are laid, beginning at the lowest point on the claim, and into these the enriched gravels are worked by means of wing dams and shoveling.

As the work progresses up stream additional boxes are supplied.

**HYDRAULICKING.**—In the upper channels, as at the Woodin claim, the gravels have been attacked where the present canyon crosses the former stream bed. The gravel at the mouth was hydraulicked away and sluice boxes laid on bedrock, everything being worked into these sluice boxes by the powerful stream from the hydraulic nozzle. The large boulders are transported to the mouth of the channel by a trolley moving on a cable, which extends the length of the workings.

**MINING BY ELEVATORS.**—Where there is insufficient fall in the creek or where deep pot holes occur, which necessitate a lifting of the gravel, bucket elevators are used. A pit is first sunk to bedrock, into which a sump is excavated, and in this the wash collects, to be elevated to the sluice boxes above. When sufficient space is cleared, a small sluice box placed in the bottom of the pit collects most of the coarse gold.

**SLUICE BOXES.**—The boxes used in the pits are usually 12 feet in length, tapering from a width of 18 inches at the upper end to 14 inches at the lower end, thus allowing them to fit into one another. The larger sluice boxes used above surface are 2 to 3 feet wide and from 50 to 100 feet long.

Riffles of several sorts are in use. An ordinary form is made by fitting round blocks 4 inches thick, sawed from logs 1 foot or more in diameter, into the boxes. Another style consists of poles placed  $\frac{1}{2}$  inch apart lengthwise in the bottom of the sluice box. Still a third sort is made of sawed strips of wood placed crosswise and set at an angle with the bottom of the box, so as to overhang on the up stream side. It is customary to have two or three sets of the pole style at the head of the sluice and below these the block riffles. All of the riffles are held in place by wedges of wood, so that they can be removed for the cleanup which begins with the uppermost set of riffles—the concentrates collecting on the lowest box.

**WATER SUPPLY.**—The flow of water in the different creeks varies with the seasons, and also during the day. Most of it comes from glaciers and snow fields, and on warm, sunny days it is usually one-third less in the morning than in the afternoon. The high water season is usually in the middle of summer, not in the spring, as might be expected on account of the melting of the snow. Low water is during the months of May, June, October and November. In the winter most of the creeks freeze over and are covered with snow, but a small stream continues to flow under the ice. Porcupine creek has a flow varying from 2000 to 5000 miners' inches per minute, and an average fall of 6 feet per hundred, or a total of 2200 feet in 7 miles of its course.

**FORESTS.**—The timber consists chiefly of hemlock, spruce, a few cedars and occasional pines, besides an abundant growth of cottonwood on the river bottoms. The lower hills and mountain slopes are usually wooded to an elevation of 2000 or 2500 feet above sea level. During the winter months the sawmills are supplied with logs not over 2 feet in diameter, mainly of spruce, and in early spring these are sawed and used for buildings, flumes and sluice boxes. A dense undergrowth of weeds, known as "devil's club," and of alders, covering the lower portion of the hills, hinders walking and makes prospecting difficult.

**TRAILS AND TRANSPORTATION.**—The usual route to

Hydraulicking Under the Edge of a Glacier in Alaska.

Bucket Elevator Working in Bedrock Sump.

were made by Mix, Finley and Wiley. They camped near Bowlder creek, and found traces of gold in the stream gravels. Fording the Klehini to Porcupine creek, a mile above Bowlder, they discovered richer gravels and obtained small nuggets of gold. After locating Discovery and the three claims above, which has since proved to contain the richest deposits in the district, they returned to Haines Mission to record their claims and obtain supplies. As a result of these discoveries nearly a thousand prospectors are said to have visited this creek during the autumn of 1898 and the spring of 1899.

**LOCATION OF CLAIMS.**—Creek claims, 1500x600 feet, were staked to the head of the Porcupine and its tributaries, McKinley, Marble and Grizzly creeks, and a number of bench claims were located on the hillsides, some of them several hundred feet above the creek bottom. Other tributaries to Klehini river were prospected and many locations made, though the majority of these have since been abandoned, partly because of their position on the Canadian side of the provisional boundary of 1900.

**PRODUCTION.**—The gold production of the placer diggings on Porcupine creek and its tributaries since their discovery in 1898 has been approximately as follows:

Year.	Value.
1898.....	\$ 1,000
1899.....	9,000
1900.....	50,000
1901.....	110,000
1902.....	140,000
1903.....	150,000
Total.....	\$460,000

**DISTRIBUTION OF AURIFEROUS GRAVELS.**—The distribution of the deposits actually producing gold is confined to the creeks which crosscut the areas of mineralized slates, and the neighboring valleys contain no valuable amounts of gold. The auriferous gravels on the Porcupine extend to the junction of McKinley creek and up this tributary for a distance of 1 mile. Gold is limited to the lower claims on Nugget creek, and a similar occurrence may be

which could not be derived from the drainage basin in which they occur.

**SOURCE OF PLACER GOLD.**—The gold from Porcupine basin is well worn and flattened, occurring in flakes or small nuggets, but is rarely rough and irregular. Its assay values are reported to vary from \$16.30 on McKinley creek to \$17.20 on the lower portion of Porcupine creek. It is of a bright yellow color, though some of the finer gold on the lower claims has a dull bronzy appearance. Nuggets of an ounce weight are not unusual, and one piece is reported weighing 8 ounces.

It is generally believed by the discoverers and operators that the gold of Porcupine and Nugget creeks has been brought from some distant source. The supposed necessity of this view is urged from the coarseness and worn condition of the nuggets, and from the absence of coarse gold and of no more than small amounts of free metal in any of the local veins. The importance of these facts can not be overlooked in attempting to determine the origin of the gold, but it is difficult to show such outside origin, owing to the limited extent of the deposits.

**METHODS OF MINING.**—On Porcupine creek one finds the primitive methods of recovering gold ordinarily employed in partly developed placer districts. The miners have been obliged to make much out of little. With implements, such as picks, shovels, whipsaws, and canvas hose, which they are able to carry to the place of working, they build ditches, flumes and sluice boxes, and install small hydraulic plants. Under these conditions the richest deposits are sought out and worked, though frequently with little economy. When available pockets have been exhausted work comes to a standstill, claim holders cease developing and do only annual assessment work, with the expectation of eventually selling out to companies who can consolidate interests and mine on an extensive and economical basis. During the last few years, however, several small sawmills have been erected by different parties, large flumes have been built, and hydraulic plants and bucket elevators installed; but equipments are still insufficient and no

\*Bull. 236, U. S. G. Survey.

the district formerly followed from Haines Mission was the Dalton trail, which has its starting point at Pyramid Harbor, on the west side of Chilkat inlet, but this road is only practicable for travelers on horses, because of the difficult fords across Taklin and Salmon rivers. Another trail leads along the east bank of the Chilkat to Wells Post, where the Chilkat is crossed by canoe, and thence along the north bank of Klehini river to opposite Porcupine. This, generally known as Throp's trail, is used during the months of low water in the early spring and autumn. During the summer months it is best to wait for a favorable wind and sail up stream. Native canoeemen are always available, and their services are necessary to those not familiar with the river.

Freight and supplies are generally moved in during the months of winter and early spring, when the snow and frozen condition of the streams greatly facilitate transportation. In the summer Indians are hired to transport the freight in their canoes as far as Wells Post, from which it is carried on wagons by a fairly easy route along the banks of Klehini river to Porcupine.

**CLIMATE.**—No climatic records have been kept of the particular area under discussion. The inhabitants claim that the winters are more severe than in the parts of southeastern Alaska nearer to the open ocean and more directly influenced by the Japan current. Heavy snowfalls begin late in October, and in places accumulations in the gulches do not disappear before the first part of June. The line of perpetual snow is about 5000 feet above the sea, and many of the valleys have small glaciers at their heads. During the summer months, however, the climate is more pleasant than that prevailing along the coast, and the precipitation is considered to be less.

**SUMMARY.**—The gold-bearing gravels in this vicinity are confined to the few creeks and benches within an area of 5 miles in width and 10 miles in length, extending from Nugget creek on the Salmon to the mouth of Porcupine creek on the Klehini. Belts of mineralized slates included in this area are crosscut by the streams, and from these the gold has been derived. The workable deposits vary from 25 feet to several hundred feet in width and are from a few feet to 50 feet or more in depth.

The gold-producing gravels on the Porcupine extend to the junction of McKinley creek and up this tributary for a distance of 1 mile. On Nugget creek the gold is limited to the lower claims.

The creek gravels are the most valuable; from information available they average several dollars to the cubic yard, though in local bonanzas much higher values are obtained. In the bench deposits lower values may be expected. The extensive river beds are known to contain some gold, but are of so low value that dredging would be the only profitable method of working them.

While some of the deposits on the lower claims of the Porcupine have been considerably developed, the greater number remain untouched, and to obtain the greatest yield from them it will be necessary to combine operations and work the various claims under one management by more economical methods than are at present employed.

The accompanying engravings shows mining methods in the district.

## Mineral Resources of the United States in 1903.

The twentieth United States Geological Survey annual report on the mineral resources of the country, containing the statistics for the calendar year 1903, is now available. Besides statistics, considerable descriptive and technical matter, obtained while the statistical canvass was in progress, is presented.

In 1903, for the fourth time, the total value of our mineral production exceeded the enormous sum of \$1,000,000,000. The exact figures for 1903 were \$1,419,721,569, as compared with \$1,260,509,738 in 1902, a gain of 12.63%.

The value of iron ore in 1903 was \$344,350,000; the value of the coal, \$503,724,381. The fuels increased from \$469,078,842 in 1902 to \$634,233,791 in 1903, a gain of \$165,154,949, or 35%. Every variety of fuel increased in value. Anthracite coal showed an increase in value from \$76,173,586 in 1902 to \$152,036,448 in 1903. The average price of anthracite coal per long ton at the mine was \$2.50 as against \$2.35 in 1902, the highest figure obtained up to that time since 1888, as compared with \$2.05 in 1901, with \$1.85 in 1900, and with \$1.80 in 1899.

The gain of \$159,211,831 in the total value of our mineral production is due to the large increase in non-metallic products, the metallic products showing a decrease from \$642,258,584 in 1902 to \$624,318,008 in 1903—a loss of \$17,940,576, and the non-metallic products showing an increase from \$617,251,154 in 1902 to \$794,403,561 in 1903—a gain of \$177,152,407. To these products should be added estimated unspecified products, including building, molding and other sands reported to this office, the rare mineral molybdenum and other mineral products, valued at \$1,000,000, making the total production for 1903 \$1,419,721,569, furnishing a good argument for the creation of a Cabinet Department of Mines and Mining.

## Notes on Crushing of Metalliferous Ores in the Stamp Battery in Africa.

NUMBER IV.

Written for the MINING AND SCIENTIFIC PRESS by  
F. C. ROBERTS.

It is obvious that the degree of fineness to which the ore has been reduced, when fed to the battery, not only affects the capacity of the mill, but has a very great effect upon the wear and tear of the spare parts. The factors which seem to directly affect the capacity of the mill are as follows: (1) Weight of stamp; (2) height of drop; (3) number of drops per minute; (4) height of discharge; (5) quantity of water; (6) mesh of screen. In Rhodesia, a great variation in the capacity of the stamp mill is recorded, the duty per stamp (1250 pounds) varying from 4.3 tons per day to 5.5 tons per day; indeed, as much as 6.5 tons has been recorded. The only way of accounting for this great diversity is in the nature of the ore being dealt with, or that one or more of the factors enumerated above are dissimilar, so that the records convey little unless accompanied by a statement of the working conditions.

Similarly, in referring to the mesh screen used and the degree of fineness to which the ore is reduced, it is often stated that a mill crushes through a certain mesh screen. It is clear that such a postulation conveys no definite information, unless accompanied by data covering the other factors, for it is quite possible to obtain (at the expense of the tonnage) just as fine a product, by using a 20-mesh screen as with a 28-mesh screen; it is only necessary, in order to obtain these results, to heighten the discharge or reduce the quantity of water, one or both, as will be seen by the perusal of the following figures, which pertain to an experiment, made under actual working conditions:

Tons of Water Used Per Ton of Ore.	Battery Screen Used.	Percentage of Total Tailing Passing a 60-Mesh Screen.
6.0	20 Mesh	74.5%
8.0	28 Mesh	69.4%

In recording experimental work of this nature it would be far more to the point if the statement were made that, after classification, certain percentages passed certain mesh screens.

In Africa, amalgamation does not always begin in the mortar box, although inside amalgamation has its partisans. Where practiced, the chuck blocks are lined with copper plates, and "back" plates are used, fastened to the back of the mortar box. There is a large difference of opinion existing in Africa as to the advisability of "inside" amalgamation. Personally, under the conditions existing in Africa, the writer is not in favor of this practice.

One of the main objections is that gold amalgam does not freely amalgamate, and, by reason of the violent agitation of the coarser particles of ore inside the mortar box, constant scouring is effected (in addition, a minute separation of the mercury is produced, referred to as "flouring"), and the particles of amalgam thus disintegrated are discharged from the mortar box, without being fully recovered on the plates, and even though cyanidation follows, it is not at all likely that these losses are fully recovered, as it is well known that a solution of KCy only feebly attacks mercury. It might also be considered possible that the assay value of the slime might be increased through inside amalgamation.

On the whole, in so far as this country is concerned, it may be said that more effective work can be obtained without "inside" amalgamation, if sufficient plate area be supplied, and the conditions generally are made favorable for plate amalgamation. Where "silver" is used inside the boxes, it is fed periodically, the quantity being determined by the condition of the outside plates.

Before good results can be obtained from the bare copper, it requires to be "set," which process embraces a rigid polishing of the copper, usually obtained with clean sand. The plate then freely absorbs the silver, which in turn attracts the gold particles, the whole being frequently rubbed well into the plate; when the plate refuses to become a further absorbent, it is considered to be "set."

A weak solution of KCy is often used in dressing the plates, the frequency of which process depends upon the condition of the ore, water, etc. In Africa, generally speaking, the plates are dressed four to six times per day of twenty-four hours, each plate requiring from five to seven minutes in the operation.

Judiciously used, a weak solution of KCy answers very well for dressing the plates, but it has been the writer's experience that less cyanide and more muscle would give generally better results.

It is interesting to note the amount of gold that a copper plate will absorb (having a superficial area of 60 square feet by  $\frac{1}{2}$  inch in thickness). After being thoroughly scraped, as much as 70 ounces of gold has been obtained by steaming the plate, which represented about 175 ounces of amalgam. The plate being then further subjected to scaling, assayed 3 pennyweights per ton.

It is not usual to steam the plates unless a final cleanup is being made, or a shortage of gold has occurred during the month and the plate gold is required to bring up the grade, although some millmen

contend that this softening is a periodical necessity, in order to keep the plates in good condition.

When a neutralizing agent is required in the treatment of the sand, lime is often fed into the battery, but the more common practice is to feed ground lime into the launder (automatically) below the mill.

This practice also serves another important purpose, in aiding in the precipitation, first of the fine sand before the "spitzkasten," and secondly, in the rapid precipitation of the slime.

The quantity of lime used, of course, varies with the acidity of the product being dealt with. Where, however, the above consideration is not an important one, and it is used as a precipitant, about twenty-one pounds of lime per ton of ore is used.

It is contended by some millmen that the use of lime has an injurious effect upon the plates and to a certain extent interferes with amalgamation; this inference, however, is somewhat exaggerated. Where the water question is a serious one and it becomes necessary to introduce a return system, as a precipitant alone, the intelligent use of lime is of great value. The only valid objection which the writer has observed, in the use of lime, is a certain amount of coagulation in the water pipes which sometimes gives a little trouble, while by its injudicious use it is possible to so coat the zinc shavings in the precipitation boxes that less surface is offered, producing less activity, which may be followed by indifferent precipitation.

The water question in South Africa is a very important consideration, as running streams are few and it is generally necessary to conserve water from the rains, which last about four months. The rainfall in southern Rhodesia amounts to about 30 inches annually; in and about Johannesburg it amounts to nearer 40 inches annually.

As a general statement it may be said that the consumption of water, including mill, boilers, cyanide plant and domestic requirements, amounts to 300 gallons (English gallons) per stamp per hour, or about seven tons of water per ton of ore crushed, but, in some instances, as much as ten tons per ton of ore is used.

With a modern return water system and favorable local conditions it is possible to return for use as much as 75% of the water.

Mill sampling is rigidly practiced, and varies on different properties only in the number of samples taken. Each truck or skip, as it is delivered to the mill, is sampled; in addition to which feeder samples are taken every hour, these being quartered down and returned daily. Screen and lip samples are also taken every hour.

The horizontal "built-in" retort is largely used in Africa. The amalgam is squeezed in a press, and retorts about 34% gold on the Rand fields, and in Rhodesia varies from 28% to as high as 54% gold.

The consumption of mercury upon one property with which the writer is concerned, measured over a period of twelve months, was at the rate of 12.6 grains per ton of ore crushed, and the mill recovery value of the ore was 11.9 dwts. per ton fine gold.

On a large plant, the gold returned from the mill by-products is of considerable importance, and a conservation of all products from the mill is made. The usual by-products obtained are enumerated below, together with the approximate values:

	Per Ton.
Battery Screens.....	2 to 3 grs.
Copper Plates.....	2 to 3 dwts.
Mill Sweepings.....	2 to 3 ozs.
Slags.....	20 to 30 dwts.
Crucibles.....	4 to 6 ozs.
Black Sands.....	7 to 10 ozs.

Battery chips and old mortar boxes are also subjected to treatment, and a small return is made therefrom.

In dealing with an ore with which the gold is known to be mechanically associated, it is often necessary to crush to a minute degree of fineness in order to obtain a high extraction without the aid of a solvent. To burden the stamp mill with the responsibility of obtaining this end is to sacrifice the tonnage, so that it has been largely urged that beyond a certain point it was more economical to install a cyanide plant and extract the tailing values in this way than to operate the stamp mill at so great a disadvantage. There is, no doubt, a certain amount of merit in this contention, where the operation is carried out without classification of product and no arrangements are made for recrusching.

The economical application of the stamp mill would appear to be contingent upon rapid discharge, which would result in the elimination to a great extent of that imperfection, "recrusching."

The metallurgical considerations to be observed, then, are: (1) Under what conditions the gold occurs; (2) what portions of the ore contain the gold; (3) the percentage of the total which this represents; (4) to what degree of fineness it is necessary to reduce the ore, or portions thereof, to liberate the gold values.

Having made the above determinations, the next considerations are that of economical classification and recrusching of those quantities which are of commercial value, for, beyond a certain point, the stamp mill is, no doubt, an expensive method of reducing ores.

It will be of interest to refer to the following figures, which are given in general support of the idea

of confining metallurgical treatment to amalgamation in free milling ores, and pertain to the value of slimes before and after amalgamation.

Although the treatment of slimes is largely practiced on the Rand fields, the writer is not aware of ever having seen figures showing the amount of gold actually extracted from slimes on the plates. These figures are averages of a series of determinations extending over a long period and on widely different ores.

1. Mill—Value of slimes before plates, 15 pennyweights per ton. Value of slimes after plates, 1.7 pennyweights per ton.

2. Mill—Value of slimes before plates, 4 pennyweights per ton. Value of slimes after plates, 2.25 pennyweights per ton.

It is clear that, at least in case 1, were the slimes not amalgamated it would be necessary to provide for the subsequent treatment of this product. Whether it would be possible to extract these values on the plates, when the slimes were combined with the sands and the conditions of amalgamation were the same, for both products, or whether it would be necessary to provide for the classification of the product before amalgamation and arrange the conditions to suit the product (which is quite likely) is a question worthy of careful investigation.

The loss of time in a stamp mill may be ascribed to the following prominent causes: Plate scraping, plate dressing, changing screens, shoes off, boxes choked, broken stem, lacing belts, extraction of steel from boxes.

With the exception of the first two items, it seems almost impossible to overcome the loss of time due to the other causes. With an ordinary grade of ore it is necessary to scrape the plates once in twenty-four hours; and, in most instances, it is usual to dress the plates once every four hours, so that the daily loss of time from these causes may be said to be as follows: Scraping, fifteen minutes per day; dressing, averaging seven minutes each, thirty-five minutes per day.

(TO BE CONTINUED.)

### Ajax Oil Forge.

An extended use of crude oil for fuel has had the effect of bringing out a great many devices for its use, and in the blacksmith shop especially is oil as a fuel appreciated, for the reason that it will give a much cleaner heat for welding than can be obtained

The Ajax Oil Forge.

from the best coal to be had. The forge here shown is especially designed to meet the requirements of mine shops, and for welding steels and sharpening and shanking drills, it has been found to show a saving of from 50% to 75% over coal.

The opening for the work can be reduced to meet any kind of work; as shown it is about 18 inches wide for heating drills, for sharpening with a power-drill sharpening machine, and by the use of both sides of the forge it is possible to heat 200 drills per hour, or enough to keep two drill sharpening machines running. When it is desired to reduce the heating capacity of the forge, all that is necessary is to reduce the opening by filling in with firebrick at each end.

In this forge especial attention has been given to two important features: First, the consumption of all the fuel in the oil. This is accomplished by means of a perforated air pipe under the openings on each side; the air is blown into the opening to confine the flame inside the forge and at the same time furnish sufficient oxygen to permit of the oil being completely consumed inside the forge, with the effect of making it pleasant for the operator to work near the forge, which is the other important feature.

While this forge is designed especially for sharpening, welding and shanking drills at the mines, it is

also designed for any and all kinds of general work. Its arrangement will permit of heating bolts, any round iron up to 3 inches in diameter or flat bars up to 18 inches wide, and by reducing the opening, can be used for the smallest work. It takes about five minutes to heat the forge for work at the start, and as it retains its heat through the day, it is ready in an instant. There is no carrying in of coal or carrying out of cinders, and no loss of a heat on account of a dirty fire. The last heat is just as clean as the first. This forge is sold by Harron, Rickard & McCone, 21-23 Fremont street, San Francisco, Cal.

### The Rotary Furnace for Roasting Quicksilver Ores.\*

Written by JOHN W. GEARY.

This article is intended to give some of the leading features of the process of roasting quicksilver ores as carried out at the Socrates quicksilver mine of Sonoma county, Cal.

The furnace in present use is known as the Howell furnace. This is the old Huntington roasting furnace with certain changes to fit the conditions at hand. In general usage it is termed the "rotary roaster." The roasting of quicksilver ores by this method is carried out in no other place in the world, although

White-Howell Rotary Furnace.

the rotary type of furnace has been for many years used for arsenical, pyritical and some zinc ores. But the roasting of quicksilver ores by this type of furnace is yet in the experimental stage, and as experiments of this character require much time and money it will be some years before its true value can be determined.

The furnace is made in the form of a large cylinder 50 feet in length, and with an outside diameter of 5 feet. It is constructed of several shorter cylinders of cast iron, bolted together. It is lined internally with 6 inches of firebrick. The weight of a casting of this size, together with the solid brick lining, is necessarily very great, and demands a strong foundation. The whole cylinder is supported by, and rolls upon, seven large trunnions or wheels. The ends of the furnace fit into sockets or collars which are fastened to the brickwork of the stack and firebox. The furnace is placed on an incline of 6 inches in 50 feet, in order to cause the ore to run through the furnace as it is rotated. The firebox is placed at the lower end of the furnace. It is of brick. The roaster is rotated at twenty-two revolutions per hour. This causes the ore to travel through the furnace and turns it over, exposing all portions to the heated gases passing through the furnace to the stack at the upper end. Power to operate the furnace and to run a large blower at the upper end of the condensers is supplied by a steam engine of 25 H. P.

The preparation of the ore for roasting is very simple, but must be carefully done in order to secure the best results. The ore as it comes from the mine is crushed to  $\frac{3}{4}$ -inch, which has proved to be the most satisfactory size, and thoroughly dried before feeding into the furnace. If the ore is fed in too large pieces the heat will not thoroughly penetrate the lumps; but, on the other hand, too fine ore will pack solid and prevent all particles from being thoroughly heated. However, to some extent this solid packing of the fine ore is prevented by the rotation of the furnace, and on the whole too fine ore is preferable to too coarse. The fines from the grizzly are mixed with an equal amount of coarse rock and run through the furnace.

In order to prevent the moist ore from balling into large lumps, which are baked hard by the heat, it is very necessary that the ore be thoroughly dried before charging. Moist ore also sticks in the feed pipe, and prevents regularity of feeding. As wet ore weighs more than the dried ore, the moisture also causes a very appreciable decrease in the tonnage per day due to this cause alone. The most serious objection, however, is caused by the steam from the moist ore passing into the condensers and thereby interfering with the proper condensation of the quicksilver.

The ore is fed at regular intervals through a hopper placed at the high end of the furnace, next the stack, and by gravitation and the rotary motion of the furnace gradually works its way to the lower end. During its passage through the furnace it is subjected to the heat of gases, which become more

intense toward the lower end. The ore passes in the opposite direction to the furnace gases. The draft, forced by the blower, carries with it the smoke and soot and volatile matter from the ore and fuel, including the mercury. These pass out of the upper end of the furnace into the dust chamber, where the heavier particles settle, and then on into the flues and condensers.

This method of roasting quicksilver ores is entirely different from the common one. In the ordinary quicksilver furnace of the Scott type the fire passes over and under the ore many times before it is finally withdrawn from the furnace. In the rotary furnace but one portion of the ore particles is exposed to the heat at one time, but by the rotary motion of the furnace eventually all portions are exposed, and the effect is the same as in the Scott furnace.

The capacity of the rotary furnace is comparatively small, and depends to a great extent upon the speed with which the furnace revolves. But the ore must not be run through too fast, as this will not give the ore sufficient time for a thorough burning. All ores do not require the same time in the furnace. The period of roasting varies from eight to three hours, the capacity of the furnace being in inverse proportion to the time of roasting required. In furnaces of the Scott type the ore can be left for an indefinite period if desired, and this is an advantage over the rotary furnace. The heat is not as completely utilized as in the Scott furnace. The inside diameter of

the furnace is about 4 feet, and the heated gases pass over the ore into the flue at a high temperature. Thus the heat is not applied where it is wanted, but passes on into the condensers, where it is decidedly harmful.

At present the furnace is running at twenty-two revolutions per hour. This will carry the rock through in about three hours and forty-five minutes. That the ore is thoroughly burned there seems to be no doubt, as the tailings give no trace of quicksilver either by panning or assay. The amount of wood consumed is 1.6 cord in twenty-four hours. This is about the amount required in other quicksilver furnaces, but in addition we have here the expense of considerable machinery which must be kept in repair, an engineer, and of fuel for the boiler.

Quicksilver is a metal which demands strict economic mining and reduction, since at the best the returns are small, and in order to make the business a profitable one it is necessary to figure closely on every expense item.

The condensation in quicksilver vapors after they leave the furnace is carried out in the usual manner.

As regards the success of the Howell furnace for quicksilver roasting, we are not yet prepared to state. It has been in the past, and is now, doing its work very satisfactorily as a roaster, but certain changes must be made before it will be fully adapted to quicksilver roasting, and until it has been given a thorough test for a long period of time it must still be regarded as an experiment.

### A Resurvey of the Cripple Creek District, Colorado.

Although only ten years had elapsed since W. Cross and R. A. F. Penrose, Jr., of the United States Geological Survey, made a careful study of the geology of the Cripple Creek district of Colorado, the people of that State were last year so strongly impressed with the economic importance of a scientific examination of the ground opened by mining operations during that period that they urgently requested a resurvey, agreeing to bear half the expense of the work. The re-examination began accordingly with a thorough revision of the topographic map of Cripple Creek by R. T. Evans, who acted under the supervision of E. M. Douglas. The study of the geology and mines of the district was undertaken jointly by W. Lindgren and F. L. Ransome, assisted by L. C. Graton. The examination begun in June, 1903, and the field work was concluded in April, 1904. Practically every accessible mine in the district was examined in greater or less detail. A preliminary report on the work, prepared by Lindgren and Ransome, has just been published. It is issued in advance of the final laboratory examinations and is a summary of those facts that bear upon the economic development of the region and are of immediate importance to the miners.

At the present time there are about 300 mines in

\*Cal. Jour. Tech.

the district. Many of them are idle and others are consolidated into larger properties. The elevations range from 9000 to nearly 11,000 feet above sea. The district contains two important towns—Cripple Creek, situated on the northwest side of the producing area, and Victor, on the southwest edge of the same area.

The mining methods employed in this district present few features of particular interest. Many large mines are operated by strong companies, but the system of leasing to individuals and small companies with royalty charges of 15% to 25% of the net output remains a conspicuous feature. The mining and milling expenses at Cripple Creek are high compared with those of other localities. Few of the large mines seem to have reduced total expenses below \$16 a ton.

In the course of the present investigation the geology of the district has been entirely remapped upon the carefully revised topographic base. The granites, gneisses and schists have been differentiated and outlined in greater detail than was practicable in the earlier investigation. Some necessary modifications of the earlier report in the way of stronger emphasis on the intimate genetic relationship of the rocks have been indicated.

There is nothing in the history of the district since 1894 which warrants any extension of the bounds of the productive territory as then known. Now, as then, a circle of 3 miles radius described from the summit of Gold Hill would include all deposits of known or prospective value, while the really important mines would be embraced by a circle of half that radius, with its center near the summit of Raven hill. That scattered deposits of greater or less value may be found in outlying portions of the district is by no means improbable, but the close geographic relation of the Cripple Creek ore deposits to the main volcanic center seems by this time well established. A brief review of the mines within this circle is given in this report and mention is also made of the outside mining properties.

At the time of the earlier survey the deepest shafts, those of the Moose, Pharmacist, and Anna Lee mines, were down only about 400 feet, while few of the other mines were over 200 feet in depth. The deepest shaft at present is the Lillie, which is over 1500 feet deep, although Stratton's Independence shaft, 1400 feet deep, has the lowest 'sump' in the district. The American Eagle shaft is nearly as deep as the Lillie, while there are about twenty other shafts over 1000 feet in depth, and at least 100 shafts deeper than the deepest workings of 1894. The amount of drifting and crosscutting accomplished since the earlier survey is more than commensurate with the increased number and depth of the shafts. The district is further intersected in various directions and at different levels by two long tunnels run for drainage purposes and by a dozen or more extensive adits.

The character of Cripple Creek ores, the structural nature of the deposits and the types of auriferous ore bodies found in the district, the depth of the oxidized zone and the relations of ore bodies to depth, the conditions of underground waters in the district, and the subterranean gases found in some of the mines are among the subjects discussed in this interesting report. A final chapter on the future of the district will arrest the attention of many investors.

The statement is made that the ore bodies, known or unknown, occurring below the 1000-foot zone, are probably neither so large nor so abundant as those nearer the surface. The possibility is not denied, however, that some strong fissures between the 1000 and 2000-foot levels may carry pay ore to far greater depths than those yet attained. An increased output may certainly be expected to follow each successful step in deep drainage. It is probable that the production of the district, while exhibiting fluctuations, will on the whole slowly decline. Existing conditions indicate that if the maximum production of \$18,000,000, in 1900, is to be surpassed, the increase will be due to the ore bodies encountered in the upper zone, which is far from being exhausted. This zone still contains much ore, both as parts of known ore shoots and in yet undiscovered ore bodies. It will probably contribute the most important part of the ore mined in the near future.

This report, which is listed as Bulletin No. 254 in the Survey's publications, will be distributed free of charge to those who apply for copies to the Director of the United States Geological Survey, Washington, D. C.

THE mines of the Black Hills of South Dakota produce gold, silver, copper, lead, tin, iron, tungsten and lithia minerals, mica, coal, salt, oil, gypsum, uranium minerals, feldspars, fuller's earth, brick and pottery clays, and abundance and variety of structural materials, such as sandstone, marble, etc. In addition to these, many rare minerals are known to exist in the wonderful hills, but are not mined yet, owing to lack of demand. Within the Hills there is a greater range of geological formation than is known in any other place of equal area and a greater number of ore-bearing geological horizons than are at present known to occur in any other single district.

## The Genesis of the Copper Deposits of Clifton-Morenci, Arizona.\*

NUMBER III.

Written by WALDEMAR LINDGREN.

The following appear to be the successive processes of deposition and alteration of the ore deposits of the district:

1. VEINS.—(Primary Processes.) Pyrite, chalcopyrite, zinc blende, molybdenite (rarely magnetite), sericite, quartz, rarely tremolite, diopside and epidote. Introduction of iron, sulphur, zinc, copper, molybdenum, potassium and silica. Elimination of calcium and sodium.

Processes of Oxidation.—(Action of sulphate solutions without oxygen.) Chalcocite (rarely covellite, chalcopyrite, and bornite), quartz, chalcedony, kaolin, alunite. Introduction of copper. Elimination of zinc, some iron and sulphur.

(Action of directly oxidizing solutions.) Cuprite, native copper, brochantite, malachite, chrysocolla (rarely azurite), chalcantite, limonite, quartz. Introduction of carbon dioxide. Elimination of sulphur, together with some iron and copper.

2. CONTACT DEPOSITS.—(Primary Processes.) Pyrite, magnetite, chalcopyrite, zinc blende, molybdenite, specularite, garnet, epidote, diopside, tremolite, quartz. Introduction of much iron and silica, together with copper, zinc, molybdenum, sulphur, possibly magnesia. Elimination of carbon dioxide and probably some lime.

Processes of Oxidation.—Limonite, malachite, azurite, cuprite, rarely native copper and chalcocite, copper pitch ore, chrysocolla, goslarite, zinc carbonate, willemite, calamine, pyrolusite, quartz, calcite, chlorite, serpentine. Introduction of carbon dioxide and additional copper. Elimination of calcium, sulphur, some zinc and iron.

CHARACTERISTICS OF DEPOSITS.—The important occurrences of deposits of carbonates and oxides in limestone and shale are found in the Longfellow, Manganese Blue, Detroit, Copper Mountain, Montezuma and Shannon mines.

They contain practically all of the oxy-salts of copper known from the district; but chiefly malachite, azurite and cuprite, with very subordinate amounts of native copper and chalcocite. The accompanying minerals consist of limonite, manganese peroxide, kaolin, and soft, yellowish material which, in a large proportion of deposits, generally proves to be decomposing and hydrated forms of tremolite, diopside, garnet, or epidote. Some deposits of chrysocolla and limonite occur, however, in unaltered limestone, and the cuprite-bearing shales are not accompanied by any gangue except a little limonite. The copper minerals are sometimes formed by crustification, but replacements in shale or lime are almost equally common.

The form is sometimes wholly irregular, but there is a marked tendency towards a tabular form following certain strata evidently favorable for deposition. The horizontal extent varies greatly, but rarely exceeds 300 or 400 feet, and the two dimensions are apt to be approximately equal. The thickness ranges from 1 to 30 feet, and is sometimes more. Regular boundaries rarely occur, and the pay ore easily shades off into the country rock. In the Manganese Blue and the Detroit mines several superimposed ore-bearing horizons are found within 300 feet of the surface. The Longfellow deposit has the form of an inverted pyramid.

Acidic porphyry is found in the immediate vicinity of all deposits. Some of them immediately adjoin the contact of the main stock, but others show decided dependence upon dikes of porphyry; one class of deposits forms tabular masses along the contacts of dikes; others, such as the Detroit, the Manganese Blue and the Longfellow, lie between two or three porphyry dikes, the latter being largely barren except for some disseminated chalcocite. Fissures antedating the oxidation, but subsequent to the contact metamorphism, have sometimes influenced the form by guiding the descending waters.

The deposits may be found in any of the Paleozoic horizons between the Coronado quartzite and the Cretaceous beds. They frequently crop at the surface, azurite appearing to resist decomposition quite vigorously.

Driving laterally, or sinking deeper from these ore bodies, is apt to develop hard limestone with typical contact metamorphic minerals and scattered pyritic ores. The very confident conclusion has been drawn that the majority of these deposits have been formed by the oxidation of irregular or tabular masses of low-grade pyritic ores, such as the lower mine-workings have disclosed in such abundance, for instance, in the Yavapai mine.

An enrichment accompanied the oxidation, both on account of reduction in volume and introduction of additional copper as sulphate. The oxidation does not reach the water level, which is far below the present workings, but acts most irregularly, sometimes leaving fresh metamorphic limestone near the surface and again penetrating along fissures to a depth of 400 feet.

The above explanation does not fit all of these

\*Abstract Trans. Am. Inst. Min. Engs.

deposits, for some are unaccompanied by evidence of contact metamorphism and have probably primarily been formed by the action of thermal, vein-forming waters, and others are entirely of secondary origin, being deposited in shales and in the clays along important faults by migrating sulphate solutions. The oxidation of the present ore bodies followed the faulting movement and probably began at a rather early epoch of Tertiary times.

FISSURE VEINS AND RELATED DEPOSITS.—Fissure veins with a northeasterly or northerly trend, but of no great individual length, follow the entire length of the porphyry stock, but are especially developed between Morenci and Metcalf and on Copper King mountain. The most prominent lode system at Morenci extends for about 2 miles, and consists of a number of shorter linked and branching fissures, forming two belts slightly curved towards the south-east. One of them lies in porphyry, within a few hundred feet of the contact, and comprises the principal mines of the district—the West Yankee, the Humboldt and the Copper Mountain. The other and parallel system traverses the metamorphic rocks a few hundred feet southeast of the contact.

Outcrops are very poor, frequently wholly unrecognizable, and it is most difficult to trace the veins on the surface. Low-grade malachite, chrysocolla, and brochantite ores are contained in the outcrops of some veins. Large masses of limonite, while common enough in the oxidized contact metamorphic deposits, do not usually occur in the vein croppings.

Underground exposures always show one or more well-defined walls frequently polished and striated. The faulting movement on these fissures is slight.

In the majority of these deposits there is a central vein which ordinarily is up to 4 feet wide, but may sometimes expand to 50 feet. It is composed of nearly massive sulphides, and closely follows the fissure. In the porphyry this is surrounded by a much wider zone of altered rock, which may constitute ore. The central vein and the altered zone are together characterized as a lode. In almost all of the veins the following vertical distribution of ore is noted:

Surface Zone—From 50 to 200 feet deep from the croppings. Contains oxidized copper minerals or is barren.

Chalcocite Zone—From 100 to 400 feet in vertical extent; possibly more in places. Contains chalcocite and pyrite.

Pyritic Zone—Begins from 200 to 600 feet below the surface. Contains pyrite, chalcopyrite and zinc blende.

It has been shown that the minerals of the upper two zones have been derived from those of the pyritic zone by processes of direct and indirect oxidation; that the chalcocite is wholly formed by replacement of pyrite effected by solution of cupric sulphate; that secondary covellite, chalcopyrite and bornite only occur in very small amounts. Also, that the surface zone is derived from the chalcocite zone by its direct oxidation. It has further been emphasized that the pyritic zone is generally very poor; that the chalcocite zone produces the richest ore, and that the surface zone is always poor and sometimes barren.

The pyritic part of the veins is, with good reason, believed to represent the primary deposition of sulphides along the fissures. It contains a small amount of quartz gangue with intimately intergrown pyrite, zinc blende and chalcopyrite. The two last-named minerals are present only in small quantities; molybdenite also occurs. A well-defined foot wall is usually present, while the hanging wall may be more or less indistinct or represented by several subordinate fissures. The deposition seems to have been chiefly effected by metasomatic replacement of crushed and sheeted porphyry, or metamorphic rock. The zone of altered rock surrounding the vein consists of sericitized and pyritic porphyry when the vein is in this rock, and may then be very wide. In the hard, metamorphic limestone and shale this zone is narrow and shows either an amphibolitic or a sericitic alteration and contains, besides pyrite, chalcopyrite and zinc blende intergrown with magnetite, a mineral absent from the vein proper. In the chalcocite zone, commercially the most important, that mineral has largely, but rarely wholly, replaced the pyrite, both in the massive veins and in the zones of pyritization and sericitization surrounding them at a certain depth. It is generally sharply separated from the pyritic zone, the transition taking place within a surprisingly short distance. Below this limit, evidence of chalcocitization can only be found along fissure planes. The uppermost part of the chalcocite zone is invariably the richest. The massive pyrite veins form pure, dull black chalcocite, or a mixture of pyrite and chalcocite. This constitutes high-grade ore with more than 5% of copper—ranging up to 70%—while the pyritized porphyry turns into low-grade ores with from 2% to 5% of copper.

To these large bodies of low-grade ore the recent great development of the district is due. In some mines the chalcocite begins almost at the surface; these are generally on the lower slopes, or in the bottoms of canyons. At Morenci, situated high up on the hills, the depth from the surface is rarely less than 200 feet. The depth on the vein attained by the chalcocite zone from the level where direct oxidation begins to the upper limit of the pyritic zone varies greatly; it is sometimes less than 100 feet,

while under Copper mountain the average would somewhat exceed 200 feet. Directly below the summit it is 300 feet, and its lower limit in some cases has not yet been reached. In general, the upper limit would be represented by a curved line somewhat less convex than the contours of the mountain. The lower limit seems to be flatter, but great irregularities exist, due no doubt to exceptional conditions of circulation of surface waters.

The great bodies of low-grade ore are almost wholly confined to the lodes of porphyry, and the pay zone generally contracts greatly when contact metamorphic shales or limestones are entered. Slopes of low-grade ore range from a few feet to 100 feet or more in width; many are 200 feet long and have been stoped for the same vertical distance. The great body of concentrating ore between the two Humboldt walls, which dip against each other, is about 500 feet long, up to 200 feet wide, and has been stoped 200 feet high. Values gradually decrease on both sides unless, as sometimes happens, confined by fissures on one or both sides. The limit is thus usually simply determined by the lowest grade of ore workable.

The ore shoots of Copper mountain are thus materially different from those usually found in gold and silver veins. Their greatest extent is horizontal rather than vertical and their size depends more upon conditions of circulation of surface waters than upon the primary distribution of copper in the vein. Prospecting for reserves must proceed laterally rather than seek extreme depth.

The surface zone is always richest near the lowest limit of oxidation where cuprite and native copper form from chalcocite. The upper part contains poorer ores of malachite, brochantite, etc., and may be entirely barren.

In the Copper mountain veins the chalcocite apparently changes directly to cupric sulphate and other copper oxy-salts are practically absent. The pyrite remains, in part, rusty and accompanied by limonite, until near the surface, where it finally disappears. The surface zone is thus directly derived from the chalcocite zone by gradual erosion and oxidation, indicating that the latter is not a very recent development.

Two of the principal faults of the district cut across the Morenci veins and dislocate them. Some of the ore bodies are clearly faulted, so that rich chalcocite ore is brought opposite leached and barren surface rock. Brecciated zones accompanying this faulting contain fragments of chalcocite ore. In all, the evidence is pretty clear that at least a part of the chalcocite zone had already been formed when the faulting took place, and that, consequently, the beginning of chalcocitization and oxidation must be placed in the earlier or middle part of the Tertiary times.

Description of chalcocite ores from other districts state that the secondary sulphides develop to a point just below the water level. In none of the important mines in this district has the water level been reached; it is probably far below the present workings. Chalcocite may now form in the upper part of the zone away from fissures and faults in places, where sulphate solutions are slowly descending and free oxygen scarce, but I doubt very much whether it is now forming in the lower part of that zone. I regard the chalcocite zone as formed about an ancient, gradually receding water level. During the early Quaternary that level was evidently several hundred feet higher than at present, but the occurrences of the chalcocite appear to require a still higher stand, such as existed during the probably moist climate of the middle Tertiary.

The payable deposits, as a rule, lie at high elevations and no large deposits have been opened on the lower slopes of Chase Creek canyon or along its bottom. The lower down on the slope a deposit is located the nearer to the surface will the chalcocite zone be found. Chalcocite ores do occur, in fact, in veins along the bottom of Chase Creek canyon, but the mineral shows only as a slight coating on pyrite.

Chalcocite ores and oxidized ores forming a "stock-work" of seams in porphyry—at Metcalf mines—or in quartzite, as in the East Yankee mine, or occurring as disseminations in porphyry dikes—West Yan-

kie lode and Shannon mine—in general correspond to the descriptions of the altered zones surrounding the veins. They presuppose earlier sericitization and pyritization effected by primary vein-forming solutions.

(TO BE CONTINUED.)

### New Uses for Cement.

A company has recently been formed at Saginaw, Mich., for the construction of works to manufacture shingles of Portland cement, says the Cement Age. The method of manufacture is described as follows:

### Mining in the High Sierra of California.\*

Throughout the world the mines are confined to no particular geological horizon, nor to any definite altitude, but valuable deposits of mineral are found in rocks of all ages, and of almost every kind. In Alaska, the payable ore deposits, at some places, come down to the waters' edge at sea level, and in California and Colorado valuable mines are found at varying altitudes up to over 14,000 feet. In other States, the altitude of the mountains seldom goes

Stone Bridge, With 80-Foot Span, Near Lake Tahoe, Cal.

A County and State Bridge on the Sierra Highway.

The shingles are made of Portland cement over a metal vertebra or reinforcement that terminates in loops at either side for nailing securely, but not rigidly, to resist the action of the elements. They are made  $\frac{1}{2}$  of an inch thick at the butt and slightly tapered. They can be made of any width, shape or color and handled and shipped as slate. They may be used to replace worn-out wooden shingles or slate and are highly ornamental. They compare favorably in price with slate and the best wood shingles.

The process of manufacture is unique. The molds pass on a moving belt. The shingles are placed in a shelf rack for thirty minutes, and then the molds are removed by a single process. The shingles are left in the yards on open racks to mature.

higher than 10,000, but it is demonstrated in both North and South America that mines exist up to altitudes as high as men can work to advantage. In Colorado, most of the mines are at altitudes above 7000 feet and a great many are at 10,000 feet and over, so the high, snowy mountains have no terror for the miners of that State, but in California the greater part of the vein mining is carried on at altitudes between 1000 and 3000 feet, and in many instances the mines are situated in pleasant valleys, surrounded by, or near, fertile farms and meadows. To the California miner of the foothill region, the idea of mining up near the summit of the snow-clad

\*See illustrations front page.

Sierra is abhorrent, notwithstanding their inviting coolness during the hot summer days. Still, there are valuable ore deposits in the high Sierra, some of which have been developed, to a limited extent, in past years and which to-day offer inducements to capital superior to those found in many distant lands.

The great drawback in the development of the mining industry in the Sierra is the lack of inexpensive transportation, but that the topographical difficulties are easily overcome is already demonstrated in many places. Good roads, substantially built, are in existence and it only requires a repetition of the effort heretofore made to extend these highways, or to construct new ones, to reach the various mining districts.

The accompanying engravings illustrate several

in first cost, but usually increases the expense of making subsequent permanent improvements.

The mining districts in the Sierra region of California are somewhat scattered, but are found from Lassen county to Inyo. Some of the most noted are in the Sierra Buttes section, in Sierra county, at Lundy and Tioga in Tuolumne county and at several places southward along the summit of the range. In Inyo county, there are a number of old camps where mining was formerly carried on, when conditions were not as well understood as at present. Among the more recent developments in this region are those of the Bishop Creek company above referred to, in the high ridges about the head of Bishop creek, in the central range of the Sierra Nevada, in Inyo county. Until recently, there was neither road

by the commercial results obtained when equipped with machinery and operated. It is claimed that numerous samples assayed returned from \$1 to \$60 in gold and a little silver, and that the zone, or lode, from which these samples were taken exceeds 300 feet in width. As the development is superficial as yet, it will probably be necessary for large amounts of the ore to be treated in reduction works of proper construction before the average values can be arrived at.

The metallurgical treatment is also a matter remaining to be determined, as is usually the case where the values are almost wholly confined to the sulphides present. As free gold is not claimed to be abundant, except in the superficial portions of the lode, it is probable that concentration and cyaniding will be important factors in the reduction of these ores.

The success of this new enterprise in the high Sierra will doubtless be the signal for renewed activity in that region, and it may be anticipated that when the possibilities of that region are better understood and demonstrated the Sierra region will become the scene of an active, prosperous, and long-enduring industry.

## Water Rights in California.

NUMBER V—CONCLUDED.

Written for the MINING AND SCIENTIFIC PRESS by  
SAMUEL C. WIEL.

LOSS OF RIGHT.—Water rights may, it is true, continue indefinitely; but they may likewise come to an end in several ways; and the chief of these are abandonment, adverse use and eminent domain.

1. Abandonment is a question of intention, to be drawn chiefly from the acts of the owner. If the owners disperse, the mine for which they used the water being worked out, and two years go by without their doing anything, they have abandoned their water right (32 Cal. 26). If they make a parol of it, it is a sign that they have abandoned it; in *Grizesa vs. Terwilliger*, 23 Cal. Dec. 313, it seems to have been considered even to be absolutely an abandonment. But this, it seems to the writer, should be regarded as only a conditional abandonment—that is, one depending on the validity of the attempt to dispose of the water right; and of no effect if the object of the parol sale is not carried out; just as in 106 Cal. 660 at 762, an owner abandoned an old ditch and used the water through a new one which, it turned out, he had built on another man's land without right. This, it was held, gave no right to use the water in the new ditch, but the right to use it in the old ditch was not necessarily lost.

The water must be continually applied to the beneficial purpose for which it was appropriated—a failure to do so is an abandonment (C. C. 1411). Up to five years the failure to use it is not conclusive and may indeed be explained away—it is a question of intention. But after five years it is conclusive. The intention may be drawn from lapse of time alone as well as from affirmative acts of the owner.

"In this State, five years is the period fixed by law for the ripening of an adverse possession into a prescriptive title. Five years is also the period declared by law after which a prescriptive right depending upon enjoyment is lost for non-user; and for analogous reasons we consider it to be a just and proper measure of time for the forfeiture of an appropriator's rights for a failure to use the water for a beneficial purpose.

"Considering the necessity of water in the industrial affairs of this State, it would be a most mischievous perpetuity which would allow one who has made an appropriation of a stream to retain indefinitely, as against other appropriators, a right to the water therein, while failing to apply the same to some useful or beneficial purpose. Though during the suspension of his use other persons might temporarily utilize the water unapplied by him, yet no one could afford to make disposition for the employment of the same, involving labor or expense of any considerable moment, when liable to be deprived of the element at the pleasure of the appropriator and after the lapse of any period of time however great.

"The failure of the plaintiffs to make any beneficial use of the water for a period of more than five years next preceding the commencement of the action, as found by the court, results, from what has been said, in a forfeiture of their rights as appropriators." (Smith vs. Hawkins, 110 Cal. 122 at 127.)

There is an abandonment of whatever runs waste after use. When the owner has made all the use of the water he wants, and lets the waste run off, the waste is abandoned, and the owner no longer has any right to it. If it finds its way by natural channels into another creek, the owners there have a right to it (3 Cal. 249). If he digs a ditch to drain away the water because it interferes with mining the

Heavy Retaining Wall on State Highway in the Sierra Nevada.

phases of road building in the high Sierra. One illustrates the result of private enterprise, near Camp Hassau, in Inyo county, Cal. Here a temporary bridge of logs and rock has been quickly constructed, at small cost, over a mountain stream, to facilitate the development of the mines of the Bishop Creek Con. G. M. Co. The other engravings show a wooden-truss bridge, built by the county authorities of El

nor trail in this portion of the Sierra, and these conditions ordinarily form a sufficient handicap to prospecting, unless some remarkable discovery be made, which attracts attention to the vicinity. The mines have been taken up near the North and Middle forks of Bishop creek, from 16 to 20 miles southwest of the village of Bishop, with which they are now connected by wagon road. The lode upon which

Bridge Construction in the Sierra Nevada, Near Camp Hassau, on Bishop Creek, Inyo County, Cal.

Dorado county, on the Lake Tahoe road, by its side is the handsome stone structure in course of construction by the State. The engravings show the false work beneath the 80-foot stone arch, which will be removed as soon as the work has advanced sufficiently to justify it. A fourth illustration is that of a road graded around a jutting spur of the mountain, the lower side being sustained by a substantial retaining wall of dry rubble. Several miles of this kind of work have been done on the Lake Tahoe road, and the same kind of work may be accomplished in almost any locality where it becomes necessary to build a highway, whether for interstate commerce or for the convenience of mine operation. One mistake the earlier road builders made was that of sustaining the lower side of the roadway by means of rock-filled cribs of logs. This is cheap

these locations have been made and development commenced is a broad zone of gneissoid rock, in which is found disseminated sulphides of the base metals, with gold and silver. This belt, or zone, parallels the Sierra in a northwest-southeast direction. The illustrations on the front page give a good idea of the picturesque region, which abounds in glacial lakes, running streams, moraines, striated rock surfaces and other pronounced features of glacial action. The sulphide minerals occur in finely disseminated grains throughout the semi-schistose rock, which forms what the manager of the Bishop Creek Co.—Ali A. Hassan—believes to be a great mineral belt, which he has called the "Sister Lode," probably in compliment to the Mother Lode. This lode, or zone, possesses no definite walls, but is rather a zone of mineralization which will probably be defined

bed of the stream, he has no more claim to it (21 Cal. 374). But it is always a question of intention. If such discharge of water is made not because it is waste, but for convenience in handling it, intending at the time to recapture it at some lower point, it is not abandoned. For example, water can be discharged into a stream as a link in a ditch line and taken out again, though there are prior appropriators on the same stream. It is not abandoned where there is an intent to recapture it. (C. C. 1413, 11 Cal. 143.) "In the case at the bar the channel of the south fork of Jackson creek is used as a connecting link between the Amador county canal and the ditch of the defendants. The water from the canal is emptied into the fork with no intention of abandoning its use but for the sole purpose of supplying the ditch. There may be some difficulty in cases like the present, in determining with exactness the quantity of water which parties are entitled to divert. Similar difficulty exists in the case of a mixture of wheat and corn, the quantity to be taken by each owner must be a matter of evidence. The courts do not, however, refuse the consideration of such subjects, because of the complicated and embarrassing character of the questions to which they give rise. If exact justice cannot be obtained, an approximation to it must be sought, care being taken that no injury is done to the innocent party. The burden of proof rests with the party causing the mixture. He must show clearly to what portion he is entitled. He can claim only such portion as is established by decisive proof. The enforcement of his right must leave the opposite party in use of the full quantity to which he was originally entitled." (Butte C. & D. Co. vs. Vaughn, 11 Cal. 143.)

An abandonment of waste covers, however, only the specific water that has been actually allowed to run to waste. The incoming water still remains at the entire disposal of the owner of the water right, who may so use it that none of it thereafter runs off as waste at all, or so that it runs off in a different place where the lower claimants no longer can get it. The latter have no right by estoppel to have the abandonment continued, even if they built expensive flumes to catch the discharge (30 Cal. 290, 80 Cal. 181, 108 Cal. 72). Of course, it must be remembered that this applies to claimants basing their rights on use of abandoned waste only. Those who, below stream, have rights of appropriation to a surplus of the natural stream itself, instead of claiming only waste, will be protected, as has been set forth elsewhere.

2. Adverse use. By one allowing another to divert all or part of the water for five years, the right is correspondingly lost to the former and acquired by the latter (32 Cal. 26, C. C. 1007). The adverse use must be made with a claim of right, hostile to the true owner (27 Cal. 360); it must be open and in plain sight, so that one has a chance to prevent it; it must be uninterrupted (27 Cal. 360, 32 Cal. 26). In such a case it is said that a grant will be presumed to have been made to the man who has been so using the water (25 Cal. 392, 104 Cal. 140); though that is merely a fiction of the law. It is not really a grant as a reward of adverse diligence; it is merely that the law will not look into claims that are "outlawed," a punishment for delay.

3. Eminent domain may justify the taking of the water right by the State for public use, on the payment of a just compensation, but it can not be taken without compensation, nor for a use that is not a public use (Cal. Constitution Art. 1, S. 14). Irrigation is such a public use, if the irrigation is for the benefit of extensive farming neighborhoods, and statutes authorizing the taking of streams for such purpose were upheld in *Lux vs. Haggin* (69 Cal. 255). Use for water supply is a public use (Cal. Constitution Art. XIV, S. 1). On the other hand, mining is not a public use, and the Legislature could not authorize water to be taken from private owners to run a group of mines (63 Cal. 72). This difference is probably a sound one, for irrigation builds up the State permanently and makes new gardens and homes out of waste; but mining, it must be acknowledged, is precarious; the more the mines are worked the less there is left; the tendency is to temporary benefit as against the permanent filling out of the State that we see following irrigation on all sides to-day.

**RIPIARIAN RIGHTS.**—It would not do to close an outline of this subject to-day without some words on riparian rights. The law of appropriation is now being more and more crowded by the other system. The two come in contact in many places, some of which we have pointed out, such as the right to appropriate the surplus over what belongs to an upper riparian owner, the right of lower riparian owners to the surplus over a prior appropriation, the right of occupants of land always to be protected in their riparian right against later appropriators. The field is an old and extensive one, on which there is far more decided law than on appropriation; yet here, viewed only as an accessory to the latter, a few words must suffice.

Unlike an appropriation, riparian rights need no act of the owner to acquire them; they attach to the land bordering on the stream of their own accord. The right thereto is a natural right. In ancient times when the law was being shaped the use for drinking purposes was in mind, and to deprive the land owner

of that was not to be thought of. It is a natural right, similar to the right to support from land adjoining, uninterfered with by excavation such as would cause it to cave, a natural attribute of the land itself in its natural state—natural in the sense that it is part and parcel of the land, acquired by virtue of ownership of the land, without any special formalities of any kind (69 Cal. 255 at 390, 126 Cal. 135).

It is usufructary solely and independent of title to the water or the bed of the stream, though the riparian owner usually owns one-half of the bed of the stream. That is, this natural right is one to use the water, not to own it (69 Cal. 255). The kinds of water to which it attaches are, in general, water-courses, lakes and, in California, percolating water (Katz vs. Walkinshaw, 141 Cal. 116). Though it may be necessary to use some other name for the landowner's right in the last case, the principles are the same. Probably the right to-day extends to subterranean streams also (132 Cal. 204), though there is some doubt as to this (53 Cal. 578). But the rights do not extend to mere diffused surface water (69 Cal. 255).

The characteristic feature of riparian rights is that the purpose, amount and manner of use is limited in all directions, so as to be within the reasonable needs of the land to which it attaches.

Reasonable uses include two great classes, ordinary uses and artificial uses (113 Cal. 182). The former includes household use, drinking purposes, watering of domestic animals, etc. For these purposes it is reasonable to take all there is, and lower claimants cannot complain (69 Cal. 255; 116 Cal. 587). It is to supply the ordinary needs of life on the land. But unusual needs, it must be noted, are not within this; watering large bands of cattle are not within the ordinary uses for which the whole can be consumed (69 Cal. 255 at 407). The artificial uses are more restricted in the extent allowed. They include such things as irrigation and the running of machinery. For these it is never reasonable to take all (77 Cal. 66). What is a reasonable amount for such purposes is a question to be decided in each case. The surplus over what is actually consumed must be restored to the stream (69 Cal. 255, 126 Cal. 135).

If the water is not enough for continual use by all, no one of the owners has a right to deprive the others of it on that account for any of the artificial uses; unlike appropriators, the riparian rights of all owners through whose land the stream flows are equal in this. A court of equity will in such a case apportion the water so that each can use all for a time, or assign to each the continual use of his share only, of what there is (113 Cal. 182, *Miller vs. Dondero*, 26 Cal. Dec. 211). It is said that this will be done with percolating waters as well as other kinds. (Katz vs. Walkinshaw, 141 Cal. 116.)

The use is not only limited to the reasonable needs of developing the land, but it must be the land to which the right attaches that it is used for—not for neighboring, distant, or, as it is called, "non-riparian lands." Water cannot, under the doctrine of riparian rights, be used to irrigate non-riparian lands merely because their owner also owns riparian land (77 Cal. 66). What lands are so far from the stream as to cease to be riparian is a question in each case. It is certain that lands beyond a watershed, whence the water could not flow back to the original stream, are non-riparian; and no such use taking water beyond a watershed is sanctioned by the common law of riparian rights (113 Cal. 142, 126 Cal. 135).

The manner of using it must likewise be reasonable.

It must not so accelerate or diminish the flow or change the quality that it prevents a reasonable use by other owners, for all are equal in this respect. For example, in 137 Cal. 39 it is said that if trees are cut and thrown into a stream, decaying and unfitting the water for domestic use, the lower riparian owner can have an injunction. Any unreasonable use is actionable immediately, because it violates the natural rights of others, even if they are not using the water themselves (117 Cal. 539). No one has a right to use another's property without his consent, however little use it may be to its owner.

Riparian rights may be lost by adverse use, in the same way as an appropriation may be (126 Cal. 135; 101 Cal. 242). They are also subject to a taking by the State, under the power of eminent domain, in the same way (69 Cal. 255). But they cannot be lost by abandonment, because of the essential difference between appropriation and riparian rights. The former is conditional on continued beneficial use, but the latter is absolutely attached to the land. The former arises from a special grant by the Government; the latter from the land itself, as a natural right. And so, riparian rights remain though the water is put to no use at all (108 Cal. 72). And even if a later appropriator lower down has made use of the water, he cannot complain when the riparian owner starts to use it thereafter (126 Cal. 136).

Many features of the law of riparian rights are elaborately considered in the leading case of *Lux vs. Haggin* (69 Cal. 255).

**CONCLUSION.**—The law of water rights in California shows, more than any other branch of the law, the changes through which California has gone and is now going. It shows how in the early days the miner dominated in the view of the law, getting the then new right to ownership by appropriation established in his favor because the lack of water in mining regions demanded it. How then this new right developed as a favor from the Government, held only so long as beneficially used, an instrument developing the State itself. How the State has more recently grown in other lines, no longer so strongly dominated by mining interests, and has been limiting its indulgence to them; as the rule that a parcel sale is ipso facto an abandonment shows, constructing the law of appropriation more and more narrowly. How the common law of riparian rights has gained the ascendant with the growth of agricultural interests, and causes the rule which is in derogation of it to be less liberally dealt with. Curiously enough it shows the agriculturist favored on the very same grounds that originally were used to favor the miner—public policy founded on the scarcity of water in California. Judge Heydenfeldt's opinion in *Irwin vs. Phillips*, 5 Cal. 140, establishing the law of appropriation, and Judge Shaw's in *Katz vs. Walkinshaw*, 141 Cal. 116, applying the principles of riparian rights to percolating water, are founded both on public policy arising out of the scarcity of water in California, yet reaching almost opposite conclusions.

Taken altogether it shows that the law develops not because the old rules meet with unforeseen natural obstacles, but because they meet with a new development of the people themselves, fitting a natural scarcity of water which has remained unchanged, to the new pursuits in which the people at large engage. But this readjustment should be guarded so as not to unwarrantably interfere with mining, as the new law of underground water, especially, threatens to do.

Bouery's Safety Attachment.

### Bouery's Safety Attachment.

The Joshua Hendy Machine Works of San Francisco, Cal., have added another improvement to their double-jointed ball-bearing giant. The addition of Bouery's safety attachment (patented), illustrated herewith, is designed to add materially to the efficiency of this giant, the intent being to insure safety to the operators and enabling work to proceed without possibility of interruption on account of breakage of any kind—a great advantage where gravels are encountered which are partially cemented and require great pressure to insure absolute disintegration and frequently at a long distance from the bank or wall of gravel. Under such conditions, if the men directing the stream are afraid of the breakage of the giant, they are constantly watching the machine, rather than the bank, their attention being drawn from the spot most demanding it that the best results be obtained. The manufacturers claim that Bouery's safety attachment makes the break-

age of a giant by working pressure impossible, and that the operator of the giant carrying such safety attachment can feel secure against accident and that the stream under his direction does the maximum amount of work.

The manager of the Lagrange Hydraulic G. M. Co., at Minersville, Triunty county, Cal., has four of these improved giants working under a pressure of 450 to 550 feet, and since their installation he writes that he has not had to stop one minute on account of accident. He says: "My mind is now relieved of the feeling of responsibility, which I consider an important matter to a mine manager."

The Joshua Hendy Machine Works of San Francisco, Cal., show illustrations of this improvement and invite correspondence from all interested.

## Mining and Metallurgical Patents.

PATENTS ISSUED JANUARY 3, 1905.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

METHOD OF PRECIPITATING METALS FROM CYANIDE SOLUTIONS AND REGENERATING THE SOLUTIONS.—No. 778,547; L. E. Porter, Camp Rochester, Cal.

Process of separating metals from alkaline cyanide solutions and regenerating solution, which consists in treating solution with zinc, calcium hydrate and salt of ammonia which will react therewith to liberate ammonia, separating precipitated metals, and adding alkaline carbonate to precipitate part of the zinc as double carbonate of zinc and calcium.

CONCENTRATOR.—No. 778,847; F. M. Dillon and W. G. Wilson, Denver, Colo.

Concentrating table provided with corrugated surface with groups of riffles running whole length of table, one of groups being located at gangue discharge side or edge of table, last named group being high at feed end of table, tapering downwardly for about two-thirds of length, and then gradually rising again at concentrate discharge end or tail of table.

METHOD OF SMELTING ORE.—No. 779,037; J. Gayley, New York, N. Y.

Method of smelting ore, which consists in subjecting ore with carbonaceous fuel to blast of dried air,

burden of fuel being less than normal burden by amount materially greater than that which would be required to dissipate eliminated moisture.

METHOD OF FORMING BLOCKS OF ORE FOR METALLURGICAL PURPOSES.—No. 778,899; A. Ronay, Budapest, Austria-Hungary.

Method of rendering material capable of use for metallurgical purposes suitable therefor by converting it into blocks by means of pressure and exposure of blocks to action of combustion gases containing carbon, which consists in subjecting material, which may be in finely granulous form or in certain cases in form of powder to pressure increasing gradually to high degree (for example 1000 to 2000 atmospheres), so that air entirely escapes from material during pressing operation, and pressure is only carried at last stage to such degree as to render material plastic, whereupon, for purpose of increasing their firmness, blocks are exposed for short time to action of combustion products containing carbon at temperature which prevents any fritting.

ROCK OR LIKE DRILL.—No. 779,017; W. Wilson, Cleator Moor, England.

In rock drill, combination of cylinder having axial way through back thereof, hollow piston working within cylinder, hollow rifle-bar working within hollow of piston and formed of shorter length than hollow, hollow piston rod fixed with piston, hollow chuck removably fixed with piston rod and adapted to receive hollow bit, pipe connected with water supply exteriorly of cylinder and passing through and fixed with cylinder end and loosely passing through bore of rifle-bar and entering bore of piston rod and stuffing box beyond end of rifle-bar within hollow of piston for forming fluid tight joint between pipe and piston and piston rod.

ROLLER CRUSHING MILL FOR ORES.—No. 779,045; George Johnston, San Francisco, Cal.

In roller crushing mill, base frame with pan, die ring, and edge rollers running on said die ring, in combination with fixed hollow central standard firmly secured to base frame, forming central conduit for ore supply and lateral support for revolving part, with outlet passages in fixed standard at bottom through which ore is delivered to crushing path from inner side at multiple points.

ROTARY FURNACE.—779,119; H. C. Davey, San Jose, Cal.

Ore roasting apparatus having in combination plurality of inclined revolvable cylinders each having conical receiving end forming close joint through masonry in which it is turnable, enlarged head fixed to discharge end of cylinder, open at both ends and having projecting flange surrounding outer end, stationary head abutting outer end of first-named head and open at both ends, and having annular channel around interior of inner end to receive surrounding flange, stationary head having chute extension at lower end, furnace communicating with opening in outer end of stationary head and delivering products of combustion thereto and to ore, open uninclosed receiver between chute of stationary head and conical inlet of succeeding cylinder, and thrust bearings to maintain joint between conical inlet and masonry bearings consisting of annular beveled rings on cylinder and corresponding beveled pinions journaled at right angles with cylinder axis.

MINE CAGE.—No. 778,919; P. Thielmann and J. Meisenburg, Duisburg, Germany.

Mine cage comprising in combination with cage frame, loose platform on frame, downwardly projecting catches loosely fixed in platform, nut on upper end of catches, two parallel or cross axles rotatably mounted in bearings on lower surface of platform, curved levers pivoted on ends of parallel axles and projecting with upper ends through platform, connecting rods connecting lower ends of each pair of curved levers and safety bars at side of cage consisting of upright supports fixed to cage frame, suitable bearings at upper end of same, axle mounted in bearings, horizontal levers fixed to end of axle, connecting rods linked to levers and push rods loosely resting on platform with lower ends and linked with upper ends to other end of connecting links, there being eyes fixed to uprights serving as guides for vertical push rods.

GOLD SAVING APPARATUS.—No. 779,365; E. S. Kelley, St. Joseph, Mich.

In gold saving apparatus, cylindrical bucket having outlet opening in side and adapted to contain quantity of mercury; funnel having contracted discharge opening facing away from outlet and arranged to be submerged in mercury in bucket, discharge opening being located at center of lower end of bucket; and inclined amalgamated plate extending from lower end of funnel to edge of outlet opening in bucket, upper edge of plate being curved to conform to curved wall of bucket, and lower edge of plate being raised above bottom of bucket.

## MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

The preliminary figures upon the production of gold and silver in the United States in 1904, submitted to the director of the mint, show:

	1904	
	Gold, Value.	Silver, Fine Ozs.
Alaska	\$ 9,000,000	184,320
Arizona	4,250,000	3,400,000
California	19,000,000	1,380,000
Colorado	26,000,000	12,500,000
Idaho	1,960,000	7,000,000
Kansas	9,700	97,400
Montana	4,970,000	12,750,000
Nevada	5,140,000	4,500,000
New Mexico	248,000	180,000
North Carolina	115,400	13,000
Oregon	1,300,000	132,000
South Carolina	113,200	600
South Dakota	7,270,000	185,900
Texas	454,400	454,400
Utah	4,700,000	10,500,000
Washington	310,000	200,000
Wyoming	40,500	13,600
Totals (not including minor States)	\$84,551,300	53,603,000
Klondike	10,300,000	.....
Nome (included in Alaska)	4,878,500	40,300

### ALASKA.

The Record Miner describes a quartz belt extending from Windham Bay, 75 miles southeast of Juneau, to Nowell City, 70 miles northwest of Juneau. At Windham Bay, the Alaska G. M. Co., California-Alaska G. M. Co., Golden River M. Co., Helvetia G. M. & M. Co., Windham Chief G. M. Co., and others are doing development work. Quartz in places has been followed for 25 miles north to Sumdum, where several low-grade properties are being worked on a small scale. Snettisham, 15 miles north, on Snettisham Bay, has a 20-stamp mill, owned by the Alaska Snettisham G. M. Co., of which J. N. Tisdale is president. The mine has been operating for several years. The mineral belt at this point is cut by Snettisham Bay, and a number of promising properties in the vicinity are being worked. Locations have been made along the line of the lode between Windham and Snettisham, proving that the formation is continuous. The belt is next cut at Takou harbor, where the Pacific Cold Storage Co. has a plant for the canning and icing of fish. Several mining locations have been made in the vicinity, and the belt has proved continuous between the last two points. The country between Windham and Takou Harbor is covered with moss, underbrush and devil clubs, and is very thickly timbered, preventing the rapid development of the section. North of here many locations have been made as far as Sheep Creek, the next point where active mining operations are being carried on,  $\frac{1}{2}$  miles southeast of Juneau. A 30-stamp mill is in operation. At the head of Gold creek, which empties into Gastineau channel  $\frac{1}{2}$  mile northwest of Juneau, in the Last Chance and Silver Bow basins, the Alaska Perseverance M. Co., adjoining the Sheep Creek property on the northwest, and the Groundhog group, owned by the Nowell Co., are being developed. The Alaska-Juneau Co., one of the associate companies of the Treadwell management, has a 45-stamp mill, and has two crosscuts, 800 feet apart, which show 1200 to 1400 feet in width of pay ore. Nearer Juneau, the Ebner G. M. Co. have had a 15-stamp mill operating for nine years. Adjoining the Ebner property on the northwest is the Humboldt group, on which a 10-stamp mill is built. From Sheep creek to the Humboldt claims, the mineral belt is unbroken, and is from 500 to 1400 feet in width, being covered with many locations. The Perseverance Co. has crosscut the formation for 2500 feet, and 1400 feet of this is in pay ore. A raise has been made for 300 feet in pay ore, the croppings being 1600 feet above the tunnel. The raise is being constructed to tap the workings 1000 feet above the present terminus. All ore in the Ebner, Alaska-Juneau and Perseverance companies is free milling. The Sheep Creek mines carry 40% of the values in silver. Opposite Juneau, on Douglas Island, are the four groups of the Treadwell mines, owned by the Alaska-Treadwell G. M. Co.; the Seven Hundred and Ready Bullion mines, owned by the United G. M. Co., and the Mexican, owned by the Alaska-Mexican G. M. Co. On Lemon Creek,  $\frac{1}{2}$  miles northwest of Juneau, the Lemon Creek Co. is hydraulicking. Between the Ebner and Lemon Creek groups, a number of prospects have been discovered. Twelve miles northwest from Juneau the Montana Creek or Montana Basin group of properties are 10 miles farther from salt water. At Tee Harbor, 20 miles northwest from Juneau, the mining zone is 6 miles from salt water. One group of claims at that point was recently bonded for \$60,000. The Eagle River M. Co., on Eagle river, 25 miles from Juneau, with B. L. Thane as superintendent, has a 20-stamp mill. Yankee Cove, 5 miles northwest of the Eagle River mines, the Alaska-Washington G. M. Co., B. M. Behrends, president; M. Kelly, vice-president; H. R. Shepard, secretary, and W. Denby, treasurer, has eight claims adjoining the Bessie properties, owned by the Shelton syndicate, 600 feet of tunnel have been run under the ledge, and a camp built for twenty-five men. Berner's Bay is a large indentation of the coast, cutting the mineral belt 55 miles northwest of Juneau. Many locations have been made in the vicinity. The Jualin has a 16-stamp mill and has yielded \$300,000, but the management was compelled to shut down last year because of a flow of water. Large pumps will have to be installed to handle the flow, and this will probably be done during the coming season. At Nowell City, 75 miles northwest of Juneau, the Kensington mines have been handed by the Nowells to J. McDonald, formerly superintendent of the Treadwell mines, for over \$1,000,000. A crosscut tunnel, when in 1200 feet, struck the Eureka ledge 500 feet below the surface. The ledge at that point was 48 feet in width, and carried an average value of \$8 per ton. The devel-

opment under the new bond carried the tunnel in 1800 feet, when the Kensington ledge was struck, showing a width of 96 feet, and the ore averaging \$6, the ledge being tapped by the tunnel at 1400 feet below the surface. The ledge has been drifted 180 feet each way from the crosscut tunnel and the ledge again crosscut at these points, showing about the same width as in the main tunnel and a maintenance of values. This property has at present a 70-stamp mill, but the new management contemplates the installation of 500 stamps in the near future.

### ARIZONA.

#### Cochise County.

(Special Correspondence).—The Mitchell Development Co. state that if \$7500 is not forthcoming the affairs of the company must be wound up. Two drill holes had been completed, showing mineral, and a third partly completed when the work was suspended on account of the lack of funds. The directors think the proposed drilling should be completed and some winzes sunk. S. Mitchell is president and general manager and J. Piper is superintendent at Bisbee. The company has 660 acres in Montezuma canyon, Huachuca mountains. Country rocks are red shale, quartz and limestone, with granite porphyry intrusions. Gasoline hoists are used because of the aridity of the region. The plant of the Southwestern S. & R. Co. at Benson has been completed. Another 250-ton water jacket for copper ores will be put in. The smelter will be running by January 15. Bisbee, Jan. 9.

#### Gila County.

(Special Correspondence).—The large tunnel of the Starlight mine, operated by the Tri-Bullion S. & D. Co. at San Carlos, is in 1500 feet and has cut 18 feet of copper ore 1000 feet below the surface. The mine is shipping ore regularly to the smelter at El Paso, Texas. J. C. Erman, engineer in charge, will put in a concentrating plant and an air compressor. San Carlos, Jan. 9.

(Special Correspondence).—A gold strike has been made in the properties of the Lake Superior & Arizona Co. at Superior, 27 miles west of Globe, in the Carleton tunnel, 320 feet below the outcrop. Globe, Jan. 9.

#### Maricopa County.

(Special Correspondence).—F. E. Withey, manager, is putting a power plant and hoist on the property of the Grand Traverse & Arizona M. Co. at Cave Creek. He is developing the thirty claims of the company and has a 140-foot and a 75-foot shaft sunk on the vein. It carries good values in gold, copper and silver. Cave Creek, Jan. 9.

(Special Correspondence).—B. Johnson continues to ship gold from his property near Morristown. J. H. McCabe has discovered wolframite north of Phoenix, about 40 miles from the railroad. R. A. Roberts is working a gold property in the Vulture district. The ore will be hauled to the river, where there is an arrastra. The Mexican mine in Cave Creek district is being worked. W. E. Williams is working a claim near the Union mine, north of Phoenix. De Mund Bros. are working a copper property in the north end of the White Tank mountains, getting shipping ore. The Hassayampa M. & M. Co. have put a whim on their property in the Picacho district, northeast of Morristown. Phoenix, Jan. 10.

#### Mohave County.

The Paymaster mines have been sold to the Victor Paymaster M. Co., represented by F. M. Hamilton of Los Angeles, Cal., and V. P. McDowell and A. M. McDuffee of Chloride. The Paymaster mine is in Paymaster basin, 1 mile north of Cerbat.

The Samoon mine, 4 miles east of Chloride, has been equipped with a hoist, air compressor and drills. L. Hoffman of Chloride is superintendent.

#### Pinal County.

(Special Correspondence).—Gold has been found at the Superior mine, near Silver King, which has formerly produced silver and copper ore. Prospecting for silver is being continued near the Silver King mine. Silver King, Jan. 9.

(Special Correspondence).—At the El Dorado M. Co. on the Gila, near Dudleyville, men are working in the shaft, having sunk 60 feet, and work on the tunnel which is being run to connect with it is being crowded. Dudleyville, Jan. 9.

#### Yavapai County.

(Special Correspondence).—The Treadwell smelting plant at Mayer is completed and will blow in when the ore bins are completed. It has a capacity of 250 tons, having a tuiere dimension of 42x120 inches. On the Queen mine dump of this company there are 4000 tons of ore ready roasted for treatment. The main shaft of the Hackberry is 400 feet deep. Steel-bottomed, broad-gauge ore cars have been ordered. Their 3-mile railroad is finished, touching the Hackberry, Boggs and Queen ground, with terminus at Arizona City, where it connects with the main line of the S. F. P. & P. system, which conveys the product to the new smelter at Mayer. The ore bins for the shaft of the United Verde Copper Co. at Jerome have been completed. Furnace No. 1, which has been down for the past six weeks undergoing general repairs, has been started up, furnace No. 2 being closed down for needed repairs. J. A. Stevenson has discovered mercury in Copper Basin—as red sulphide of mercury (cinabar). Mayer, Jan. 9.

Recognizing the need for deep sinking, the Eureka G. & C. M. Co., after completing assessment work on their claims, 7 miles south of Jerome, are now sinking on the main shaft. C. W. Woods is president, H. M. Gibbs secretary and H. Gilmore superintendent. The Pittsburgh-Jerome will sink 500 feet before crosscutting. C. R. Ewing of Jerome has let a contract for shaft sinking on the Surprise, Lookout and ninety-six claims.

The White Mountain G. M. Co. will put in a 20-stamp mill at its mine near Congress Junction. The power is to be for forty stamps and a cyanide plant. The com-

pany has fifty men at work grading a mill site and a road from Congress Junction to Wickenburg.

### CALIFORNIA.

C. T. Deane, secretary of the California Petroleum Miners' Association, has issued a report by districts of the crude oil production of California during 1904, showing a total of 28,423,700 barrels, which places California far ahead of any other State in the Union, and far ahead of any country except Russia:

District.	Production, Barrels.
Fullerton	876,000
Puente	204,000
Whittier	750,000
Los Angeles	1,080,000
Newhall and Ventura	540,000
Sumnerland	80,000
Santa Maria	750,000
Kern River	376,000
Sunset and Midway	17,500,000
McKittrick	1,050,000
Coalinga	4,544,000
Sargents	12,700
Halfmoon Bay	1,000
Total	28,423,700

#### Alameda County.

The American Magnesite Co., owning magnesite deposits 30 miles from Livermore, will haul the raw material to Livermore and ship to Oakland, where the Rose Brick Co. is to put up a plant at Sessions basin to manufacture brick. In the calcining of the material carbonic acid is thrown off, for which the Pacific Carbonate Gas Co. has been formed to handle it. It is also proposed to manufacture tiling from the magnesite rock by the Plastic Construction Co. H. C. Stillwell, Hayward Building, San Francisco, is manager.

#### Amador County.

The new 20-stamp mill of the South Eureka at Sutter Creek is almost completed, and when it starts the old 20-stamp mill will be hung up. The Zella chlorination works at Jackson have shut down, the supply of sulphur being exhausted, and probably will not start up until the completion of sinking operations and the erection of the new hoisting machinery. The Empire mine in Murphy's gulch, adjoining the Amador Queen No. 2, near Jackson, is being developed under the management of R. S. Green.

#### Kern County.

W. Houser has bonded the Excelsior mine, between Randsburg and Johannesburg, from Fifield, Barton Bros., J. Thompson and T. Seehold of Randsburg.

#### Nevada County.

The Union Con. G. M. Co., near Nevada City, G. A. Nihell, superintendent, is pumping out the shaft below the drain tunnel and will commence sinking. The drain tunnel is in 150 feet beyond the incline.

An agreement has been arrived at in the litigation between the Champion and the Home G. M. Cos. by which the continuance of work in the mines is permitted. Work was stopped a few weeks ago, when the Champion Co. sued the Home Co. for \$300,000 damages and asked for an injunction to prevent the Home Co. from taking ore out of what the Champion Co. claimed was its property. The Home Co. retorted by instituting a suit against the Champion Co. and operations had to be suspended on both sides, causing the laying off of many workmen. The attorneys on both sides have signed an agreement by which the disputed ground is definitely described, and it is stipulated that ore shall not be removed from it during the pendency of the litigation. Operations elsewhere may be resumed. Either party may continue the work of exploration in the disputed ground, but no stoping shall be done, and whatever ore is encountered in the exploratory work shall be stored and be subject to the determination of the controversy in court. Each party gives the other the privilege of inspecting and surveying its underground works prior to the termination of the trial and the submission of the case.

#### Plumas County.

W. J. Droege of Greenville is developing the Johnny Bull mine by a tunnel 7 feet in the clear. The Claybank tunnel above La Porte has struck the gravel channel.

#### Shasta County.

A 5-ton hoisting plant is being put up at the Midas mine at Harrison gulch. The hoist in use will be placed on the 700-foot level.

### COLORADO.

(Special Correspondence).—As the ore in a mine begins to show signs of "playing out," the management begins to cast about for the best method of prospecting the undeveloped portion of the property. For several years past some of the larger mines have kept one or more diamond drills busy doing prospect work. Some of the recent discoveries in the Leadville district are largely due to the diamond drill. Without their aid it would have been almost impossible to prospect the amount of ground that has been prospected in Leadville the past year or two. To sink a shaft or drive a tunnel in the Leadville district was out of the question for prospect work, on account of the water and terrific expense a mine would be under in doing prospect work through tunnels or shafts. With the diamond drill they have been able to sink several hundred feet at hut little expense and at the same time have been enabled to tell the class of ore the drill passed through. With the aid of the diamond drill a manager is able to prospect ahead of his development work and keep a large amount of work mapped out. The superintendent of the U. S. Mint at Denver has received orders to hold all bullion in storage and accumulate a stock for coinage purposes. The State Legislature will be asked to pass a measure making arbitration of all labor difficulties compulsory on both sides. Should such a measure be adopted, it will no doubt be of benefit to all concerned, as it will do away, to a certain extent, with many of the long drawn out contests. The reports received from the various camps for the coming year are encouraging for a good season. Denver, Jan. 8.

## GILPIN COUNTY.

Below is given a table of the milling plants with the location and number of stamps in each mill:

Gilpin County Mills and Location.	Stamps.	Slow.	Rapid.
Chimax, Black Hawk	25		
Fullerton, Black Hawk	33		
Hidden Treasure, Black Hawk	75	10	
Meade, Black Hawk	40		
Polar Star, Black Hawk	40		
Yacile, Black Hawk	35		
Boston & Denver, Black Hawk	80		
Gilpin, Black Hawk	50		
Rocky Mountain, Black Hawk	25		
New York, Black Hawk	50	20	
Raudolph, Black Hawk	50		
Penn., Black Hawk	50		
Iron City, Black Hawk	25	25	
Bonanza, Chase Gulch	25		
Periko, Gamble Gulch	35		
Peterson, Lump Gulch	15		
Avon, Nevada Gulch	30		
Mount & Pal, Pine Creek	10		
Gregory & Buell, Mountain City	45		
Blue Grass, Phoenix	10		
Cheladonia, Wide Awake	10		
Totals	488	300	

A total of 788 stamps in the county, with an average capacity of 1000 tons every twenty-four hours, to which may be added a daily tonnage of 100 tons at the Rocky Mountain concentrator, which, with a daily average of about 100 tons delivered at the sampling works, would make the total tonnage of the camp about 1200 tons per day, with all the plants in full operation. With regard to proposed improvements in quartz mining, the Denver Republican reports that the Gold Dirt M. Co. has decided to erect a modern cyanide plant, with an initial capacity of 100 tons per day, but the mill will be constructed so that the capacity can be doubled if needed. This mill is to be ready for operation by April 1st. It is reported that a custom mill of twenty-five or fifty tons is to be erected at Rollinsville during the early part of the year. The Boston-Occidental M. Co. has expended about \$50,000 on its test plant in Denver and the experimental plant at American City, in the Pine Creek district. The officers claim to have perfected their dry crushing process, the ores being crushed to a 15-mesh and after that wet concentration is resorted to. The company is arranging to cyanide the concentrates. The plant will have a daily capacity of 100 tons, and it is claimed that the new mill is adapted to the sulphide ores of that section. The company figures on erecting a larger plant in Mammoth gulch during the coming year, to handle the product from the mines near James Peak.

Chicago people, interested in the Golden Rod M. & M. Co., are figuring on the erection of a mill to treat their property on Silver creek. Denver and Eastern people, who are operating the Cold Spring tunnel property in Boulder Park, are said to be figuring on the erection of a 20-stamp mill on South Boulder creek during the spring months. The Black Hills & Denver M. Co. is getting estimates on the erection of a 100-ton concentrating plant for the treatment of the product from its Park tunnel properties, and is busy installing a water-power plant for heavier operations.

The Otto Shatz M., L. & D. Co. has a group of four claims in the Lake district, Central City. G. L. Singer is superintendent. R. A. Hastie of Denver is president and general manager.

## LAKE COUNTY.

During 1904 Leadville produced:

	Value.
Gold, 62,152 ounces, @ \$20.67 per ounce	\$1,283,476
Silver, 5,435,442 ounces, @ \$7.24c per ounce	3,108,392
Lead, 46,561,743 pounds, @ .04375c per pound	2,037,076
Copper, 4,638,728 pounds, @ .125c per pound	579,841
Spelter, 85,623,200 pounds, @ .0546c per pound	4,675,027
Manganese, 5,000 tons, @ \$5 per ton	25,000
Total	\$11,708,812

## MINERAL COUNTY.

During 1904 Creede produced: Gold, \$491,408; silver, \$3,624,154; lead, \$1,842,796; zinc, \$213,158; total, \$6,171,516. The total tonnage output from the Creede district for the year was 90,878 tons.

## ROUTT COUNTY.

A company organized by Dr. E. A. Hewitt of Denver will purchase 250 acres of copper mining property on Farwell mountain, east of Hahn's Peak, for \$37,500, from W. McCormick of Elk River, A. Royal and E. F. Carr of Hahn's Peak, G. Withers of Steamboat Springs and G. P. Anderson of Hayden, and will put in a concentrating plant.

## SAN MIGUEL COUNTY.

At the Butterfly-Terrible G. M. Co. mines and 30-stamp mill, near Ophir Loop, fifty-five men are at work; twenty stamps are operated by steam and ten by water power. The 2900-foot tunnel to the Ida vein has been driven 170 feet. J. F. Keating has charge. B. Wells, manager of the Smuggler-Union M. Co. at Telluride, has granted A. Fitzpatrick, E. J. Carter, A. Cushman and A. Darch a lease on ground in the Sheridan workings on the same vein as the Smuggler-Union mines, and the lessees have started active work. The three principal lessees on the Smuggler-Union properties—Wagner Bros., King & Lindsey and the Telluride Leasing Co.—are each employing nearly 100 men which, together with those employed by the company, including timbermen, engineers and tramwaymen and the smaller lessees, make about 350 at work in the property. From 350 to 375 tons of mineral is sent down over the tramway every twenty-four hours, and it is expected this will soon be increased to upwards of 400 tons, the maximum capacity of the two mills.

The Japan M. Co. has resumed operations on the Japan group in Savage basin, near Telluride, under supervision of B. Mattiotti.

The Gold King Basin M. & M. Co. has driven a cross-cut tunnel which has cut the vein. The property is under the management of W. M. Herrington, formerly of Coudersport, Pa. W. G. Shaw is president; W. Conahle, vice-president; C. L. Peck, secretary; W. M. Herrington, treasurer and general manager, and C. DeWitt of Telluride, mine superintendent.

## SUMMIT COUNTY.

A contract for 1000 feet has been let to E. T. Brooks of Breckenridge by the French Creek G. M. Co. The tun-

nel is now in 400 feet and is 5x7 in the clear. Electric power plant is installed with which the electric drill and the Sturtevant exhaust blower will be operated. An electric plant has been put in the Country Boy tunnel to operate the blower for the Juniata vein. The Lincoln G. M. Co. may put in an elevator plant on the Mekka ground in the early spring to elevate the ground to the sluice boxes and to wash the gravel to bedrock until the sluice box is extended.

An estimate of mining in Summit county during 1904 states:

	Value.
Gold from placer mining	\$115,000
Gold from ores	230,000
Silver from ores	177,816
Lead from ores	113,061
Copper from ores	6,293
Zinc from ores	107,835
Total	\$750,005

Placer mining on Blue river and its tributaries near Breckenridge has been active during 1904. The American Gold Dredging Co. has dredge boats operating the Swan river-hed deposits and uses hydraulic giants for the high bars of Gold Run. The Reliance Gold Dredging Co., organized by B. S. Revett, is building a modern \$50,000 gold dredging boat to operate on the bedrock deposits of French gulch. Tests were made by sinking 8-inch churn drill holes to bedrock. The Summit Banner Placer M. & M. Co., L. Kingsbury manager, will operate the Con. Iowa gulch placers this season with hydraulic giants, supplied under a head pressure of 203 feet through a 22-inch pipe line from a storage reservoir.

## TELLER COUNTY.

(Special Correspondence).—There are twenty-four leasers at work on the Hull City placer ground, controlled by the Independence Cen. G. M. Co. This property will be closed down on Jan. 12th for repairs. It will be ten days or two weeks before they will be in position to proceed with underground work. Instead of installing new pumps to handle the water, it is believed arrangements will be made with an adjoining property to pump the water.

Independence, Jan. 8.

(Special Correspondence).—C. G. Jackson, manager of the Mary Nevill Leasing Co., operating on the western slope of Beacon hill, is sinking a shaft to cut the Lenaconing dike which is known to extend through the property. Shaft is down 120 feet and will be sunk 200 feet deeper. It is believed at that depth they will be able to strike the dike as well as encounter the C. K. & N. vein which extends through the gulch. E. G. Taylor, manager of the C. K. & N. mine on Beacon hill, encountered a 3-inch streak of rich sylvanite ore a short time ago. During 1904 this property shipped 10,230 tons of ore with an average value of \$67 per ton. This tonnage was dry weight or after the moisture had been deducted.

The El Paso Con. G. M. Co., W. Bainbridge, superintendent, is handling seventy tons of assorted ore per day. This company has a double-compartment shaft. One compartment is 6 feet long by 5 feet wide in the clear and the other is 5 feet long by 3½ feet wide. The large compartment is equipped with single-deck cage, while the smaller one has a double-deck cage. Two ore cars holding 2½ cubic feet of ore are placed alongside of each other on the large cage. Much time is saved in this manner, as they do not have to raise and lower the cage when loading or unloading, as in case of the double-deck cage. After the men have been lowered for a shift no one is allowed to ride on these two cages. These cages work in balance and carry nothing but ore and timbers. Between shifts, when anyone wants to be raised or lowered in the mine, they are lowered or raised in a small single-deck cage which holds three men. This cage is operated in a small compartment adjoining the larger compartment on the right. This cage is operated by a Hendrie & Bolthoff first motion hoist. The mine is supplied with air by three 12-drill Norwalk compressors. The drainage tunnel is carrying a full head of water, although the pressure is not as strong as heretofore, as the head of water is growing smaller. The cost of the present drainage tunnel was \$85,000, and it is estimated that over \$500,000 has been saved already in pumping alone. The prospects for a larger and more efficient drainage tunnel in the near future are encouraging. Some of the companies which the present tunnel has benefited, and a larger one would still be of greater benefit, are trying to block the progress of the second tunnel, but it is believed that the objection will be overcome. The association will hold its annual meeting January 14 and officers for ensuing year will be elected. The question of a new tunnel will come before that meeting, when steps will be taken to insure the much-needed tunnel. The present tunnel still has about 100 feet of ground to drain. It is thought that it will drain all but about 35 feet of this 100 feet. When it gets to that point the pressure will be so light that it will not act. It is understood the El Paso mine will subscribe \$75,000 towards the new enterprise, and there are a number of other large properties that will come forward with their share of the expense.

Cripple Creek, Jan. 8.

Construction work has begun on the new cyanide mill that is to be put on the Little Giant Co.'s property in Pony gulch, west of Cripple Creek. Alterations are being made in the Columbine mill on the Woods properties, near Victor, which will increase capacity by the removal of the old processes nearly 250 tons daily.

The Pinto-Bison M. Co., J. O. A. Carper of Denver, manager, is operating the Free Coinage ground. They have thirty-five acres, covering the south slope of Bull Cliffs. A new shaft is being sunk on the property, in the town of Altman. This shaft, according to Manager Carper, will be 1250 feet deep when completed. A compressor plant will be installed shortly and the work in the shaft will be pushed with air drills. The shaft is 4x8 in the clear, double compartment. The object in sinking this shaft 1250 feet is to encounter the junction to the Pinto-Basalt dyke with the Wilson vein. J. Wollom is foreman. This same company will sink the Pueblo shaft to the fourth level. At present they are timbering the shaft and putting in new skidway. This shaft is down 163 feet on the incline.

Altman, Jan. 8.

## IDAHO.

## Elmore County.

D. Kirhy, manager of the Monarch mine at Atlanta, Idaho, will put in a chlorination plant. The ore is to be first roasted and then passed into a tank in which the chlorination takes place. After it has been leached the precious metals are precipitated partly by electrical action and partly on zinc.

## Shoshone County.

(Special Correspondence).—An important strike on the Black Horse group at Murray has been made. C. Manley is interested. The Silver Cliff copper mine of the Snowstorm has cut into the east and west vein at 125 feet from the surface. The Champion copper mine, in the Stevens Peak district, has geed ore in their lower tunnel, consisting of chalcopryite in a gangue of white calcite. The Monarch mine, at Murray, has opened up another hedy of good lead-silver ore. T. N. Barnard and E. J. Hunter of Wallace have headed the Knickerbocker group, in the Evelution mining district, near Wallace, for \$15,000.

The Tarbox mine, at Saltese, has crosscut 50 feet into the ledge without reaching the hanging wall. All the large producing mines, except the Hercules, have been connected to the electric transmission line from Spokane, Wash., the Morning mine being the latest to complete connections. The outlook for the Cœur d'Alene mining region for the ensuing year is bright, and it seems safe to say that under the present circumstances the district will exceed the output of last year. This year there will be several important new producers and probably higher prices for lead, silver and copper.

Wallace, Jan. 7.

## Washington County.

The Montezuma M. Co. and the Keystone-Bedie, belonging to Lewis A. Hall, have started a tunnel to tap the Black Garnet, Endline and Keystone-Bedie in the canyon on Browlee creek, ½ mile above the Ruthburg road, near Heatlh Camp.

The Beise Exploration & Mining Co. has bought the Larson placer at Resort, near Warren, and will operate it soon.

## ILLINOIS.

The coal output for the year ending June 30, 1904, was 37,077,879 tons, produced from 932 mines. The total number of tons shipped was 31,778,260. Out of a total of 49,361 men employed underground, 109 were injured.

## KANSAS.

The report of the Prairie Oil & Gas Co. shows the production of the Kansas-Indian Territory oil fields for 1904 to have been 5,599,053 barrels.

## MONTANA.

## Broadwater County.

A. C. Mason has eighty men developing the Park & New Era group, building a sawmill, and concentrator with a capacity of 100 tons per day.

After two years' idleness, operations were resumed by the East Pacific Co. at Winston last July and continued without interruption up to the last of the year, during which time the property yielded \$30,000 in gold.

## Choteau County.

The King-Barnes company mined and treated 36,000 tons of ore at its Alder Gulch property during 1904 and is equipping the shaft with a 16 H. P. gasoline engine, intending to sink deeper. Two new companies were organized for work in the district during the summer and are erecting two mills, each of which will have a capacity of 3000 tons of ore per month.

## Fergus County.

At Kendall the Kendall G. M. Co. produced 108,000 tons during 1904 and will increase the size of its mill. The Whiskey Gulch mine, near Gilt Edge, yielded 3000 tons of ore per month, and the Gold Reef yielded 4000 tons.

## Madison County.

At Silver Star the Green-Campbell Co. has sunk its main shaft 430 feet and will build a 15-stamp mill. The Bismarck-Nugget Gulch Con. M. Co., near Sheridan, worked its mines continuously during 1904 and its 100-ton concentrator and mill since early fall.

## NEVADA.

## Lincoln County.

The Nevada-Utah Mines & Smelters Co. has been formed for \$15,000,000 by J. Weir of New York City, president; E. F. Cragin, vice-president; H. Doud, treasurer; C. J. Caughy, secretary, and J. Dos Passos, general manager, to work the Manhattan, Pioche Cen. at Pioche, Nev.; also the old dumps at Bullionville and Taylorville, the Comet, Imperia and Montreal in Beaver county, Utah, and the Last Chance property at Bingham, Utah. E. F. Fruedenthal, superintendent of the Majestic C. M. & S. Co. at Milford, Utah, is a director. The Savanic and Grand Gulch mines, in the north part of this county, are preparing to ship ores. A wagon road is being built over the Virgin mountains, 40 miles from Grand Gulch, to St. Thomas.

L. Wheatley of Searchlight is developing the Duplex mine. Two shifts are in the mill and seventeen tons are being crushed daily.

## NEW MEXICO.

## Co'tax County.

The steam dredger on the Moreno, near Elizabethtown, is being repaired for operations next spring. The dredger last year produced over one-fourth of the gold credited to New Mexico. The Oro Dredging Co. operates the dredger on the Placer. R. J. Reiling is manager.

## Grant County.

The Bonnie M. Co., S. W. Malthie president and manager, is developing the Lone mine at Lordshurg, and has a double-compartment shaft down 70 feet.

## Luna County.

The Hancock property in the Tres Hermanas district

has been purchased by E. E. Burdick from the Hancock M. Co.—The Tri-State M. Co. has bought the Big Helena and Hard Times mines in the Cooks Peak district. J. E. Britton, who represents the owners, has started development work.

Santa Fe County.

The Sunny Slope M. Co. will start work on the San Lazarus in the New Placers district. J. Jackson is in charge of the machinery and G. W. Churchill is superintendent.—The Gold Bullion M. Co., near Golden, J. W. Wood manager, is installing new machinery to take the place of the old damaged by the floods last October. The company operated a big steam shovel and a Johnson washer in the Old Gulch, near the Kelly wells, 1 mile from Golden. When completed it will handle 2200 cubic yards of dirt a day.

OREGON.

A review of progress in mining in the Bohemia district during 1904 shows systematic development with little hooming. The wagon roads from the terminus of the O. & S. E. Railway have been improved, making the transportation of supplies into the district cheaper. The Oregon-Colorado M. Co. built a wagon road to its property on Anna creek to the county road near Bohemia postoffice; other roads and trails have been built, so that practically every part of the district is easily accessible either by wagon or on horseback.—The Oregon Securities Co. has its 30-stamp mill completed and a tram connecting it with the main working tunnel above. They have driven a crosscut tunnel by machine drills, 1000 feet crossing several ledges of ore, and reaching the Champion vein.—The Crystal Con. Co. is working its properties, but will wait until spring before starting its mill.—The Golden Slipper Co. has opened up fine bodies of ore.—The Riverside group on Horseheaven creek put in a Pelton wheel to run the blower for the tunnel.—At the Oregon-Colorado, contractors are at work upon a 500-foot contract, which, when completed, will place the breast of the tunnel more than 1200 feet from the mouth.—The Great Eastern, Le Roy and Twin Rock properties have been developed. The Royal Flush group and extension are being worked by A. Lundburg.—The Hiawatha M. Co. did considerable tunnel work.—W. H. Shane was developing the Pittsburgh group on the Ridge.—The Golden Rule Co., near Mineral, has been developed under management of W. Wetcher.—A 10-stamp mill, with an aerial tram of 2000 feet from tunnel to mill, was put in by Manager F. J. Hard at the Vesuvius.

Baker County.

The Huntington M. Co. has started work on the Connor Creek placings, 17 miles below Huntington. They have put in 24,000 feet of 34-inch flume and 1500 feet of 11-inch pipe and have two giants operating.

Jackson County.

(Special Correspondence).—The Golden Spike on Wagner creek is one of the Shorty-Hope group of claims owned by the Shorty-Hope M. & M. Co. of Ashland. G. S. Sanford, 130 East Terrace, Chattanooga, Tenn., is interested. The main drift is in 700 feet and the shaft is being sunk through an 8-foot vein of good ore. Ashland, Jan. 9.

Josephine County.

The Golden Drift M. Co. is putting in a 5-step centrifugal Jackson pump at its newly completed dam at Gold Ray, on the Rogue river, 3 miles above Grants Pass. Four 400 H. P. turbines have been placed for power and pipes have been laid from the dam to the Dry Diggings. The pump is designed to furnish 9000 gallons per minute under a 300-foot head to hydraulic giants at the placer mines. The company is now operating near the river with one 3-inch giant with water from Jones creek under 500-foot head. This being insufficient throughout the year, it is hoped to work with water pumped from the Rogue river by power developed by the river. F. Ray of New York is interested.—H. E. Foster of Grants Pass is superintendent at the Oregon Belle mine in the Forest Creek district.—W. H. Brevort of New York and R. N. Bishop, engineer of the Greenhack mine, have formed the Martha M. Co. to work the Seenic, Yellow Dog, Scorpion and St. Peter's claims at Greenhack. It is reported that they will put in a 10-stamp mill on the Seenic, which R. N. Bishop is developing at Greenhack.

The Blue Ledge Copper Co., working on tributaries of the Upper Applegate, intend to put in a compressor plant in the spring and to push development work on their copper shoots.—It is reported that a railroad will be built from Grants Pass to Takilma. T. W. M. Draper of Grants Pass is interested.

SOUTH DAKOTA.

Lawrence County.

F. W. Bock of Rochford has sold his mill to the Commonwealth M. Co. of Lead City. The Commonwealth Co. has driven a double-track tunnel 130 feet and will probably open the vein at about 450 feet.

The Consolidated Power & Light Co., organized by J. J. Henry of Denver, Colo., has taken over the holdings of the Belt Light & Power Co. at Pluma and the Black Hills Electric Light Co. of Deadwood, and will re-equip the Pluma plant, giving it a capacity of 5000 H. P., supplying power to mining companies throughout the district. The Deadwood plant will be dismantled and sold.—The Golden Elk Co. is developing a property near Nigger hill. A tunnel has been driven 120 feet and considerable surface work done. The company intends to put in a power plant. E. B. Sager has charge at Tinton. The Globe G. M. Co. at Lead is building an amalgamating and cyaniding plant, using Trent mills to pulverize the ore. Seventeen hundred feet of drifting and crosscutting has been completed.

The Lucky Strike M. Co. is developing a property near Perry, 14 miles south of Deadwood. A new air compressor has been put in. They intend to build a 60-stamp mill in the spring. A. L. Harris of Reedshurg, Wis., is president.—The Homestake Extension M. Co. is working between Lead and Deadwood and will build a mill in the spring.

UTAH.

Dividends declared by Utah mines during 1904 were:

Annie Laurie, \$100,000; Centennial-Eureka, \$100,000; Century, \$21,000; Daly-West, \$1,044,000; Gemini, \$150,000; Grand Central, \$175,000; Horn Silver, \$80,000; Mammoth, \$120,000; Sacramento, \$20,000; Salvador, \$6000; Silver King, \$1,300,000; South Swansea, \$3000; Tetro, \$18,000; Utah, \$4000; Utah Con., \$900,000; Uncle Sam Con., \$20,000; United States, \$200,000; Victoria, \$7500—a total of \$4,268,500.

It is estimated that during 1904 Utah produced in gold, \$6,518,036; in silver, \$7,774,979; in copper, \$7,221,756; in lead, \$5,020,550; and in quicksilver, amounting to 700 flasks, \$31,500.

WASHINGTON.

(Special Correspondence).—The Braden Copper Co. shipped to Chili the first concentrator for working copper ores ever sent into that country on the steamship Saxonia, accompanied by 1,500,000 feet of lumber for the new mines of the company. E. B. Braden, manager of the company, is in Seattle. E. W. Nash, president of the American S. & R. Co., and B. Sewell are interested in this company. Mr. Braden says: "Chili has, up to a couple of years ago, been producing only from high-grade ores, and it is our contention that we will be able to conduct a more than profitable business there if we only handle the low-grade ores. We took over our property last March, my brother, W. Braden, having left New York last January to investigate the proposition. We intend to push the work of development through as quickly as possible." The mining property is 90 miles from Santiago and the railroads carry the concentrator and machinery to within 30 miles of the mine.

At the annual meeting of the trustees of the Kearns-Montana Coal Co. the following officers were elected: President, J. W. Hill of the Northern Pacific Railroad; vice-president, J. F. Firsch; secretary-treasurer, J. L. Mercer of the Wisconsin Central. The company recently secured 2 square miles of coal lands in the Nicola coal fields, on the survey of the Canadian Pacific, and has outlined a plan of development on its properties in Montana and British Columbia and expects to soon begin shipping.—The Rambler-Cariboo M. Co. is considering an increase of its capital from \$1,250,000 to \$1,750,000 and the additional half million shares of stock will be offered at 12½c each to secure \$62,500, which it is estimated will be needed to develop the mine. All work on the Slocan silver-lead property centers in the driving of a 4500-foot tunnel to catch the lode at depth. It is in 1500 feet. The extra stock will be offered pro rata to existing stockholders and if not taken by them will be probably placed with Eastern interests.—Superintendent Case was in the city from the California mine at Republic and reports the property to be lending fresh encouragement. He explains that the shaft has been in had condition its entire length. Above the 200-foot level some very good ore has been encountered. Prospecting is now being carried on in the upper levels. At the Copper Key several teams are hauling ore to the railroad for shipment to the smelter, but the roads have been had and sleighing is only fair now. C. T. Porter is at Republic to do assessment work on the Golden Lion-Little Four claims.—J. Bourne of Portland, Or., is working the Last Chance group, between Ruhy and Loop.—The deep level in the Belcher mine at Republic, 600 feet below its apex and 1000 feet long, has entered the main ore body. A drift has been driven along the footwall.

Seattle, Jan. 9.

Ferry County.

The cyaniding plant of the Republic P. & C. Co. has been dismantled and shipped to the Crooked River M. & M. Co. at Stites, in the Buffalo Hump mining district. A carload of equipment, including crushing rolls from the mill, has been sold for use at the Sullivan smelter at Marysville, B. C.

C. T. Porter, superintendent of the Little Four and Golden Lion Con. M. Co., is developing the property, near Republic.

Stevens County.

Owners of the First Thought mine, at Bosshurg, have leased the Napoleon mine, 2 miles north of Marcus, on the Kettle river road, the ore of the Napoleon to be used for a lead flux.—At the Big Bear property, 3 miles southeast of Marcus, development work has been resumed by G. G. Reynolds of Marcus.

FOREIGN.

BRITISH COLUMBIA.

Rossland District

The tons of ore shipped and crushed during 1904 in the Rossland mines were:

Le Roi.....	132,267	Cliff.....	1,340

CANADA.

Yukon Territory.

Gates City, the new town in the Tanana, is rapidly building up.—A strike has been made on Shaw creek, 100 miles above Fairbanks. Over 100 men have gone from Fairbanks and vicinity.—In traveling between Fairbanks and Dawson this winter by way of Circle, one can eat every meal in a roadhouse and have comfortable roadhouse sleeping accommodations every night. Beds are \$1 each. The trip is made in eighteen days.—An unusual steadiness marks the situation in the Dawson markets this winter. The demand is fair, but the supply seems wholly adequate on all lines, and scarcely any variation is perceptible since the close of navigation. Eggs are 50 cents higher, to cover cost of storage.

CUBA.

The U. S. Consul at Cuba, regarding the mining industry in Cuba, says the minerals most abundant in Cuba are asphalt, copper, iron and manganese. Of as-

phalt there are rich beds to be found in the provinces of Habana and Pinar del Rio. In Habana Province are mines known as Jesus del Potosi and Santa Rosa, 1 mile south of Campo Florido. The Rodas Concepcion and Magdalena mines are at the inner end of the bay of Mariel. At Bahia Honda the Santa Elena mine has good asphalt. In Sancti Spiritus is the Pozo Colorado and Ampare mines. Union mine at Guanajay, Pinar del Rio Province, has 10,000 tons annual product; owners, Zardain & Aspuru. The Angela Elmira mine at Bejucal, Habana Province, has an annual output of 3000 tons; owners, West Indies Co. The Maria Rayon mine at Moron, Camaguey; output, 180 tons; owner, M. A. Glynn. The Amparo mine, owner Francisco Moreno, and the Desengano, owner Gerardo Abeign, both located at Sancti Spiritus, Santa Clara Province, have an annual output of 125 tons each. The copper mines in operation are at Cobre, Santiago de Cuba. The Caridad and Concepcion are owned by Maximaliano Salcedo. The Mina Grande is owned by the Cobre Mine Co. There is also copper mining in Pinar del Rio, at the Buenas Aguas, Recompensa, Union, Caridad, and the Cuha Western copper mines, in Habana Province; at Bacuranao, and at Jaruco and Minas; in Santa Clara Province, near Cienfuegos and Santa Clara City; at San Fernando and Santa Rosa, in Puerto Principe Province; the Bayatabo, between the cities of Puerto Principe and Nuevitas, the Marion, the San Antonio del Cerro, and the Cuhillas mines. In all these mines the prevailing ore is carbonate of copper, the extraction of which is found comparatively easy, because it is found at no great depth. The iron mines in operation are owned by the Spanish-American Iron Co. and the Juragua Iron Co. at Caney, Santiago de Cuba Province. The Spanish-American Iron Co.'s mines, Lola, Lola 2d, San Antonio and San Rafael, gave an output last year of 493,860 tons, while the Juragua Iron Co.'s mines, Abundancia, Firmina, Resolucion, Fomento, Jupiter, Union, Constancia and Columbia, gave an output of 235,476 tons; the total output of iron being 729,336 tons. The Vincedore and the Serallo mines, owned by the Ponupo Mining Co. at Alto Songo, Santiago de Cuba Province, produced last year 26,352 tons of manganese. The Boston mine at Caney, Santiago de Cuba Province, owned by the Standard Manganese Co., produced 6267 tons; total manganese produced during the year, 32,628 tons. At Rancho Veloz, in the province of Santa Clara, a mine known as San Juan de Motemho produced 60 tons of naphtha. In the province of Santa Clara have been located the Meloneras mine, near Guarachuya, in the district of Placetas and in the district of Holguin old gold claims have been redennounced, and the only marble of importance is that which is found in the two mountains east and west of Nueva Gerona, on the north coast of the Isle of Pines. The marble is of good quality, ranging from a good white statuary stone through various shades of blue-veined to dark gray. A salt deposit exists near Salinas Point, Isle of Pines. The annual production of the number of mines actually operated, namely, five asphalt, three copper, twelve iron, three manganese and one naphtha, give a total output valued at \$1,446,000, as follows: Asphalt, \$122,900; copper, about \$13,068; iron, \$1,146,892; manganese, \$163,140.

JAPAN.

The Mitsui M. Co., S. Mitsui, president, and T. Dan managing director, is a branch of the Mitsui Bussan Kaisha, with head offices at No. 1 Surugacho, Nihon-hashiku, Tokio, and operating the Mikke, Tagawa and Yamona mines. The Mikke coal mines, in Kiushiu, on the border of the provinces of Chikugo and Higo, near Omuta on the Kiushiu railway, with 16,000 acres, is one of the largest mining enterprises in the world. Several seams of coal occur in the field, but only the first and second seams are worked. The first seam averages 8 feet in thickness of pure, solid coal. The coal has a reddish-brown color, and is a highly bituminous coking coal, being the standard coal in Asiatic markets. The six mines of the colliery produce 3000 tons daily and are equipped with the latest and best machinery for baulage, ventilation and drainage, and everything is done to protect the lives of the miners and to maintain uniform output with a minimum amount of handling. Over 5000 miners and workmen are employed. The Tagawa coal mines, in Buzen in Kiushiu, cover 5000 acres. The total output of the Tagawa mines for 1902 was 366,520 tons. The Yamano concession, in Chikuzen, Kiushiu, with 3500 acres, produced 129,769 tons of a lustrous-black coal in 1902. It is worked from the two seams of 5 and 8 feet thickness, both of which are of similar and even quality.

Since the discovery of a gold mine in Iwate, the authorities have been prospecting and tracing the ancient gold mines in the interior and have found mines at Umegashima, Abe district, Shizuoka prefecture, at Odakimura, Chichibu district, Saitama prefecture, and at Nishizawa, 4 miles from Yumoto, Nikko. The records show that the last mine was practically worked seventy years ago, but since then has been utterly abandoned. The mine is said to have fair prospects if properly worked. It is further stated that great difficulty will be experienced in working the above mines, as they are located in the roughest parts of the ravine.

MEXICO.

Chihuahua.

Weisel & Kock are unwatering H. Losoya's Predilecta mine, at Guanacevi.—S. E. Chaipella of Hollywood, Cal., is developing the Soledad and Constancia claims, near Rio Florida or Villa Coronado. L. H. Powder, manager at the property, is sinking shafts. A. Bronimann of Jimenez and Harmon & Dillon of Parral are prospecting in the same region.

High-grade gold ore has been found in the Quehradillas silver mine, near Parral. G. Gillett is manager. The district has formerly produced nothing but silver.—J. D. Knott, owner of the Prieta mine in Parral, states that pumping machinery will be put in and the mine opened up.

The Minas Almoloaya, S. A., D. W. Shanks, general manager, and N. O. Bagge of Los Angeles, Cal., the principal owner, is working its property at Cerro Almoloaya, between Jimenez and Parral. On its different

properties there has been done 1000 feet of sinking, 600 feet of tunneling and 350 feet of drifting. A telephone line is being built from Derado station, on the Farral branch of the Mexican Central railroad, 5 miles to the mines.—The Companero M. Co., operating in the Sahuaripa district, has made a strike of high-grade ore while sinking its shaft. The property is owned by Los Angeles and Pasadena investors and M. C. Dorr is superintendent.

Corrigan, McKinney & Co. are drilling with two diamond drills on the Nueva Chihuahua mine, in Santa Eulalia, under the superintendency of J. Mitchell.—It is reported that the existence of oil along the surveyed line of the Kansas City, Mexico & Orient Railroad, between Ojinaga and San Carlos, in eastern Chihuahua, is to be proven by W. R. Hearst, J. Follanshee of New York, W. and A. Kraft and C. R. Troxel of Chihuahua.—The United States M. Co., in which J. P. Elkin and T. L. Ayers are interested, is developing the Constancia and San Antonio mines, in Parral district, and expect to put up a cyanide plant.

The Clarinas mine, near the San Francisco del Oro, in the Santa Barbara district, is shipping forty tons of ore per day to the Terreon smelter. It is owned by the Clarinas M. Co., in which N. B. Wilson is interested.

#### Hidalgo.

(Special Correspondence).—J. H. Kinkead is putting in a Kinkead mill at the Guadalupe mine, near Pachuca. It will crush ten tons to 60 mesh. Mr. Kinkead will make tests at the El Oro, near the City of Mexico.

Pachuca, Jan. 9.

#### Sonora.

(Special Correspondence).—A company, C. E. Conway of Pittsburg, Pa., president, and J. R. Smith of Pittsburg, Pa., treasurer, has bought the Guadalupe mine in the Picocho mining district for \$100,000 and propose to erect a 40-stamp mill.—The Oro Maximo Co. in the Picocho district is increasing its force and preparing to do development work on an extensive scale.—The Sonora Bonanza M. Co. in Naco elected W. M. Barker president, R. McCune, vice-president, R. E. Lopez secretary, W. Gmähling treasurer, T. T. Davis and D. Lewis directors. The report of Superintendent Henley stated that 800 feet of work had been done, that there are 5000 tons of ore on the dumps ready for shipment and that a wagon road had been completed from Iduriz, the railroad station, to the mine. It was decided to begin shipment of ore on January 10.

Cananea, Jan. 7.

Taylor & Riadon have bought the Estrella del Norte, near Metecuma, from N. Stuppe for \$30,000. They will put in a pumping plant and a mill.—It is reported that G. F. Woodward has sold the mines of San Juan de Bautista, 15 miles northwest of Metecuma.

J. Henderson, president and manager, and W. K. McKibben of Chicago, secretary of the Campana Minera de Sonora de Cobre, S. A., are visiting the copper property in the Altar district, owned by the Ohio-Mexican M. Co.

At El Oro, owned by the Coast Line Copper Co., of which J. Henderson is general manager, the Huntington mill is being hauled from Poza station to camp.

At the Babacora mine, adjoining the Chispas mine, 14 miles south of Arizpe, 150 men are employed and the 10-stamp mill is running full time. A tunnel 12x15 feet has been driven 1500 feet. R. J. Verner and W. H. Coleman of Colorado Springs are interested.

W. E. Defty, general manager, and J. C. Flores, superintendent, of La Gran Proveedora de Cobre, S. A., report that their copper mines near Caborca, in the Altar district, Sonora, are down 570 feet.

#### SIAM.

H. G. Scott reports to the Far Eastern Review that mining in Siam is confined to tin, sapphires, rubies and gold. It is under the control of the Royal Department of Mines and Geology, and prospecting licenses and mining leases may be obtained without difficulty. Gold is washed out of the alluvium by the natives in Pu Kirin, Bangthaphan, Kow Suplu and Tomoh. In the latter district Chinese workers carry on lode mining as well as alluvial. The native gold mining industry is unimportant, not more than 1000 persons being employed. Modern methods have not been successful in Siam because of the difficult nature of the country for carrying on mining by Europeans and bad management. Sapphires and rubies are the only gems of importance, though spinels, zircons, garnets and topaz are produced to a small extent. Siamese sapphires form a considerable proportion of the world's supply of this gem. Statistics, however, are not available, as there is no duty on the stones, and the work is carried on by numerous small parties of men, and even by individuals, who dispose of their findings to a number of traveling tradesmen. Siamese rubies do not command a good price, as those of good color are mostly very small, while those of good size are of poor color. Practically all Siamese sapphires come from the district of Phalin in Battambang. Rubies are worked in a small way in the same district, but the chief ruby workings are in Chantahoon and Kratt. The gem mining districts are, for the most part, exceedingly unhealthy, this fact being a great bar to European enterprise in this line. Tin is found in small quantities in the valley of the Nam Sak river and in various places in northern Siam, but all deposits of importance are from the line of granitic upheaval forming the boundary range between central Siam and Tenasserim, in the backbone of the Malay peninsula, and may be traced down to the Dutch islands of Billiton, Banca and Singkep. This great line of granite is the source of practically all the vast alluvial deposits of tin which are found in Siam and the British and Dutch East Indian possessions. Tin is being worked on the east coast at Rathuri, Bangthaphan, Langsuan, Chaiya, Bandon, Lakon, Jalor, Rangeb, Rahman, Kelantan and Tringganu, and on the west coast at Kra, Renong, Takuapar, Pangza, Takuatung, Puket, Trang, Stul, Pertis and Kedah. The total annual production is 5000 tons. The mining is in the hands of Chinese, the labor is Chinese, and the melting is locally by Chinese methods. One British and one Dutch com-

pany are working in Kedah, an American company is making a small commencement in Bangthaphan, and a British smelting company is establishing an ore buying agency at Puket. The number of Siamese and Malays engaged in tin mining is very small. There is a large field for the expansion of the tin mining industry in the Siamese possessions in the Malay peninsula, and considerable activity in prospecting on the part of European capitalists has lately been shown. At present Puket island, on the west coast, is the most important tin mining center in all the Siamese States, but Kedah, Takuapar and Renong, also on the west coast, have a considerable mining industry. On the east coast Lakon Sri Tammarat and Jalor (port Patani) are the chief centers. The most promising districts for future developments are in Kedah, Rahman, Jalor, Takuatung and Renong.

## Personal.

D. A. CAVAGNARO is assistant superintendent of the Clover Leaf M. Co., of Roubaix, S. D.

V. C. OSMONT of San Francisco, Cal., is examining mines near Porterville, Tulare county, Cal.

A. C. AIKEN of San Francisco, Cal., is in Santa Eulalia, Mexico, looking after the San Juan mine.

C. J. TEAGLE is superintendent of the Searles M. & W. Co. at Garden Station, near Randsburg, Cal.

J. S. GROO has been appointed superintendent of the Blue Jay Extension mine, in Beaver county, Utah.

S. PEACOCK has been appointed manager of the Ladd Metals Co.'s interests at Mineral and Landore, Idaho.

PH. REARDEN has gone from Baker City, Or., to assume a position with the C. C. Co., Cananea, Sonora, Mexico.

A. L. SORESENSEN has been appointed superintendent of the Jumbo, Trall Creek, Rossland, B. C., by Manager M. R. Galusha.

WM. MAGENAU has completed cyanide investigations for the Rossland Power Co., at Rossland, B. C., and is now in Denver, Colo.

A. G. HARBOUGH of the Kearsarge mine, Virginia City, Mont., will be superintendent of a reduction company at Goldfield, Nev.

J. J. BURKE of Salt Lake City, Utah, is building a cyanide and concentration plant for the Golden Eagle mine at Winnemucca, Nev.

WILLARD BAYLISS of Ironwood, Mich., assumed the superintendency of the Myers and St. Clair mines at Chisholm, Minn., on January 1.

FRED BUTLER of Salt Lake City, Utah, has been made superintendent of the Blue Fields G. M. Co. at Blue Fields, Nicaragua, Central America.

SUPERINTENDENT A. L. ROSECRANS has returned to the Standard copper mines at Clifton, Ariz., from a business trip to Tuape, Sonora, Mexico.

J. B. TOMLINSON, general manager of the Swansea M. Co., has announced the appointment of B. N. Norton as superintendent at Cananea, Sonora, Mexico.

FRED. G. FARISH of Denver, Colo., is at present in the State of Sinaloa, Mexico, where he intends spending the next four months examining mining properties and will make his headquarters at Rosario.

WM. O'SHAUGHNESSY, consulting engineer, who has built over 16 miles of rock aqueduct tunnel in the Hawaiian Islands in the past two years, returned there last week to begin another project.

C. S. MCHENRY, first assistant superintendent of the Cananea Con. Copper Co. mines at Cananea, Sonora, Mexico, has resigned and H. E. Kirk has been promoted to his place. J. Duffin has been appointed second assistant superintendent.

THE Western Society of Engineers, 1734 41 Monadnock Block, Chicago, Ill., have elected the following officers for 1905: President, E. C. Carter; vice-presidents, G. A. M. Liljencrantz, C. F. Loweth, L. P. Breckenridge; treasurer, A. Allen; secretary, J. H. Warder.

R. B. LAMB is making a professional examination of the mines and works of the Westralia Waihi gold mines at Davyhurst, W. A. Before returning to America he will make investigations into recent filter press and slime practice at Kalgoorlie and mill practice of the northern fields.

## Books Received.

Bulletin No. 240, United States Geological Survey, "Bibliography and Index of North American Geology, Paleontology, Petrology and Mineralogy for 1903," by F. B. Weeks.

The United States Geological Survey has issued "Report of Progress in the Geological Resurvey of the Cripple Creek District, Colorado," Bulletin No. 254, by W. Lindgren and F. L. Ranseme; "A Gazetteer of Indian Territory," Bulletin No. 248, by H. Gannett, and "Results of Primary Triangulation and Primary Traverse for 1903-04," Bulletin No. 245, by S. S. Gannett.

Bulletin No. 234 of the U. S. Geological Survey, "Geographical Tables and Formulas," by S. S. Gannett, is a revised and corrected edition intended for use by the topographic corps and others interested in this work. It is a handy compilation of all tables and formulas likely to be required in both the field and office work of all surveyors. The method of fixing a meridian is particularly valuable in its conciseness and completeness

with accompanying tables. The five-place tables of logarithms and circular functions are convenient and easy in use; the tables on projection and for conversion will be great time savors, as will also the stadia reduction tables. The work is accurate and will be invaluable to all surveyors as a convenient reference book. It can be had upon application to the Director of the U. S. Geological Survey, Washington, D. C.

In Professional Papers, No. 30, of the United States Geological Survey, J. R. Leiberg describes "Forest Conditions in the Little Belt Mountains Forest Reserve, Montana, and Little Belt Mountains Quadrangle," and in No. 33 F. G. Plummer and M. G. Gwessell describe "Forest Conditions in the Lincoln Forest Reserve, New Mexico." In No. 31, J. A. Taff gives a "Preliminary Report on the Geology of the Arbuckle and Wichita Mountains in Indian Territory and Oklahoma." These mountains consist of eruptive granites, gabbros and diabase dikes intrusive in Paleozoic limestones. H. F. Bain carefully sampled and assayed many prospects in quartz veins in the granite and gabbro, but found no trace of gold and but little silver, copper or lead. The granite is suitable for building purposes and the limestone for manufacture of Portland cement.

Bulletin No. 235 of the U. S. Geological Survey is "A Geological Reconnaissance Across the Cascade Range Near the Forty-ninth Parallel," by G. O. Smith and F. C. Calkins. It describes geological and forestry conditions in a wild section near the international boundary line in the State of Washington. North of where the Skagit river turns west the Cascade mountains become complex and it is proposed to subdivide them into the Okanogan mountains, Hozomeen range and the Skagit range, from east to west. It is stated that the mountains consist largely of acidic igneous rocks belonging mainly to batholithic masses, and, in a general way, they consist of a synclinorium. They are bounded by slates, greenstones and schists on the east and west. The region is a promising field for gold, silver and coal prospecting. It seems very similar to the Sierra Nevada mountain region in California.

This time has been aptly called "the age of cement." We are surrounded on all sides by streets and buildings of cement. How long will they last? According to F. H. Eno in his book on "The Uses of Hydraulic Cement," it is more durable than stone. He shows the wide application of cement in mortars, in concrete and in reinforced concrete. This book is practical in its descriptions. Certain proportions of certain kinds of sand, gravel and cement will produce certain results if rightly handled. It tells how to mix mortars, the effects of different kinds of sands, the causes of cracks, and then gives numerous examples of its application to structural and ornamental work. The millwright will find cests and descriptions of concrete construction of almost every form. A brief comparison is given of the various systems of reinforced concrete; its strength and adaptability are well illustrated by examples of its use. The whole is told so well that the book is interesting to read. The chapter on specifications is good, it embodies many well-known theories, but presents them in usable form. It forms Bulletin No. 2, fourth series, of the Geological Survey of Ohio. It is seldom that so practical a book for every-day usage is received from government sources. Information is given in a form that can be used by those who have the most need for it. It may be got from the Ohio State Geologist, Columbus, Ohio, or will be sent postpaid by the MINING AND SCIENTIFIC PRESS upon receipt of \$1.

## Trade Treatises.

Booklet No. VIII from Borden & Sellick Co., 48-50 Lake street, Chicago, graphically portrays and describes their coal-handling machinery, including their combination elevator and conveyor.

The Ridgway Belt Conveyor Co.'s catalogue descriptive of the Ridgway two-belt conveyor system will be sent to any address on request. Their address is 29 Broadway, New York City. The subject is treated in deserved detail.

"Territory Embraced by the Machinery Sales and Engineering Business of Chas. C. Moore & Co.," San Francisco, Cal., is the taking title of a calendar on a map embracing the Pacific coast from Alaska to Panama, and the west half of the United States.

Advance sheets of Catalogue No. 36 of the 1905 edition of their air compressor catalogue, from the Ingersoll-Sergeant Drill Co., 26 Cortlandt street, New York, include additional information to that appearing in the first edition, giving fine views of important installations, including those of the Cleveland Stone Co. and the Mare Island Navy Yard.

Gorgeous in quality and numerous in appearance have been the 1905 calendars received this month, but among the host the artistic coloring of the one from the Taylor Iron & Steel Co., High Bridge, N. J., stands resplendent. The "calendar" part of it is a mere caudal appendage, but the picture—"The Historian"—is a splendid piece of color work and as such deserves especial mention.

## Obituary.

GEO. F. BATCHELDER, for many years prominent in mining enterprises in Colorado, died in Minneapolis, Minn., Dec. 31, 1904, in the 77th year of his age. He was at one time president of the Mining Exchange in Denver and interested in mining enterprises in Cripple Creek and Leadville. He went to Colorado about thirty years ago from Faribou, Minn.

## Commercial Paragraphs.

THE Kilgore Machine Co. of Minneapolis, Minn., have consolidated with the A. Carr Co., of that city.

THE Pacific Hardware & Steel Co. of San Francisco, Cal., have absorbed the J. C. De la Montanya Co. of that city.

R. B. McCONNEY, well and favorably known in business circles, succeeds R. J. Cory as Colorado manager of the Allis-Chalmers Co.

THE offices and manufacturing plant of the Globe Iron Works Co. (formerly of Minneapolis), are now located at Menomonee, Dunn county, Wis. The company builds the White gasoline engine.

THE California Powder Co. has leased an entire floor in the Wells-Fargo building, 49 Second street, San Francisco, Cal., removing from their former location, 330 Market street, to larger quarters.

THE De Remer Water Wheel Co., Denver, Colo., has recently installed for the Glenwood Springs Light & Water Co., Glenwood Springs, Colo., one 4-foot De Remer water wheel to operate air compressor and electric plant.

THE Brown Corliss Engine Co., Corliss, Wis., have an order from the Illinois Steel Co. for 2000 H. P. combined vertical and horizontal Corliss engine to be established at their Joliet plant. This engine is of similar design to the engine recently built by Allis-Chalmers, which was exhibited at the World's Fair.

THE Stephens-Adamson Manufacturing Co., engineers, founders and machinists, Aurora, Ill., on January 15th open a Chicago office in the First National Bank building, corner Monroe and Dearborn streets, to better serve their Chicago trade and their outside friends and customers passing through or visiting Chicago.

COLORADO IRON WORKS CO., of Denver, Colo., report the following shipments: Six carloads of concentrating machinery to the Granadina M. & M. Co. in Mexico; one carload of special large capacity ore cars to the Cananea Con. Copper Co., also in Mexico; one carload of crushing rolls to the Montana Zinc Co. in Montana, and six improved impact screens to the Joplin district, Missouri.

THE Smooth-On Manufacturing Co., Jersey City, N. J., sends a pocket book which contains a magnet and a piece of Smooth-On iron cement sheet packing, the latter easily attracted by the magnet, showing the high percentage of Smooth-On contained therein. One of these pocket books will be sent free to any engineer upon receipt of 5 cents to pay for postage. Their Pacific coast office is 61 Steuart street, San Francisco, Cal.

ALL of the stores now occupied by the S. H. Supply Co. at Twenty-second and Larimer streets, Denver, Colo., will be consolidated February 1 and located under one roof, the company leasing for a long term of years the building at the corner of Eighteenth and Lawrence streets, formerly used as the central power station of the Denver City Tramway Co. Besides this building the company has four warehouses, twenty acres of yard room, a mile of trackage at Thirty-first street, where last year 528 carloads were shipped and received.

TURBO-GENERATOR CONTRACTS closed by the Westinghouse Electric & Manufacturing Co. during the last week of 1904 included two 1000 K.W. outfits for the Haverhill (Mass.) Electric Co., to be used in lighting and power work in that city; two 1500 K.W. outfits for the Rochester, Syracuse & Eastern Railroad, and one 1000 K.W. outfit, with exciter, for the Springfield Electric Light Co., Springfield, Mass.; also a 300 K.W. turbo-generator, with exciter, for the Northern Electric & Manufacturing Co. of Montreal. The Springfield Electric Light Co.'s contract also included two 500 K.W. rotary converters and four 300 K.W. transformers.

SMITH, EMERY & CO., chemical engineers, 83-85 New Montgomery street, San Francisco, Cal., from this time on represent the Pittsburg Testing Laboratory, Ltd., inspecting and metallurgical engineers of Pittsburg, Pa., in the Pacific coast States. Hereafter orders for the inspection of bridges, cars, locomotives, building materials, etc., at rolling mills and shops in the East and middle West can be filed with Smith, Emery & Co. All local Pacific States inspection work, physical testing and metal analysis will be done by the resident engineers and chemists of Smith, Emery & Co. The fact that this inspection bureau has found it requisite to make definite connections on the Pacific coast is another evidence of the rapidly growing importance of the trade in construction iron and steel, railroad and steamship equipment and metal industries.

THE annual dinner given by the Paraffine Paint Co. to its traveling men was held on Friday evening, December 30th, in the banquet room of the Merchants' Club, San Francisco, Cal. This is the fourth annual dinner given by this company, these dinners being given for the purpose of bringing together the factory superintendents and the men who are responsible for the selling of the goods. The company has resident agents established in various cities on the Pacific coast, the territory adjacent to these cities being covered out of central offices. Thirty representatives from different parts of the West were seated at the table. A pleasant evening was spent about a bounteous board, and the close of a most satisfactory year's work was celebrated. The utmost good-fellowship prevailed, and the gathering will no doubt prove a source of great benefit to the men and the company. The Paraffine Paint Co. is now in its twenty-first year. It has shown a remarkable growth, and its goods—P. & B. ready roofings, P. & B. building papers, P. & B. and Pabco paints and malthoid roofings—are favorably known all over the West and in all countries whose shores are washed by the waters of the Pacific ocean. Its success, while largely due to the excellent quality of the goods manufactured, is also due to the in-

telligent and energetic way in which these goods have been brought to the attention of users. The works of the company are at Emeryville, Alameda county, Cal., the railroad station being known as Paraffine. The main offices are at 24 Second street, San Francisco, Cal.

THE C. O. Bartlett & Snow Co., Cleveland, O., report the following recent sales of their different machinery: Dundee Silica Sand Co., Dundee, O., elevating and conveying machinery; Leisy Brewing Co., Cleveland, O., tube barley conveyor; Pattison Supply Co., Cleveland, O., coal conveyor; T. S. Henderson & Co., St. Louis, Mo., special cable conveyor; C. L. Holck & Co., Monterey, Mexico, mining machinery; Royal Crown Lead Co., Detroit, Mich., paint machinery; International Harvester Co., Chicago, Ill., paint machinery; Memphis White Lead Co., Memphis, Tenn., paint machinery; Moore Bros., Cleveland, O., and New York, paint machinery; Lowe Bros., Dayton, O., paint machinery; Independent Stone Co., Cleveland, O., two steam hoists and derricks; The Underwriters' Land Co., Carthage, Mo., large ore elevator; Lorain Supply Co., Lorain, O., style E rotary dryer; The Berg Co., Philadelphia, Pa., Triumph steel dryer; General Chemical Co., Cleveland, O., direct heat dryer; Brightman Chemical Co., New Brighton, Pa., salt rotary dryer; Ross Keller Triple Pressure Machine Co., St. Louis, Mo., direct heat rotary dryer.

## Latest Market Reports.

SAN FRANCISCO, January 13, 1905.

### METALS.

SILVER.—Per oz., Troy: London, 27½d (standard ounce, 925 fine); New York, bar silver, 59½c, refined (1000 fine); San Francisco, 59½c; Mexican dollars, 51c; San Francisco, 47½c, New York.

COPPER.—New York: Standard, \$15.25; Lake, 1 to 3 casks, \$15.37½@15.50; Electrolytic, 1 to 3 casks, \$15.25; Casting, 1 to 3 casks, \$14.87½. San Francisco: \$16.00. Mill copper plates, \$17.00; bars, 18@24c. London: £68 6s 7d spot per ton.

LEAD.—New York, \$4.70; Salt Lake City, \$3.50; St. Louis, \$4.12½; San Francisco, \$4.50, carload lots; 4½c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5½c; pig, \$4.85. London: £12 17s 6d long ton.

SPELTER.—New York, \$6.25; St. Louis, \$6.25; London, £24 17s 6d per ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

TIN.—New York, pig, \$29.05@29.30; San Francisco, ton lots, 30c; 500 lbs., 30½c; 200 lbs., 30½c; less, 31c; bar tin, 32½@35c. London, £131 7s 6d spot.

PLATINUM.—San Francisco, crude, \$18.50 per oz.; New York, ingot, \$19.50 per Troy oz. Platinum ware, 75@82c per gram.

QUICKSILVER.—New York, \$40.00@41.00, large lots; London, £7 15s; San Francisco, local, \$39.00 per flask of 75 lbs.; Denver, \$45.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 31½c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 19.50c; San Francisco, Plumbers', 100-lb. lots, 16.25c.

ZINC.—Metallic, chemically pure, ½ lb., 50c; dust, ½ lb., 10c; sulphate, ½ lb., .04c.

NICKEL.—New York, 55@60c per lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c per lb.; 100 lbs., 35c; 1000 lbs., 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

### STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$16.35@16.60; gray forge, \$15.85; San Francisco, bar, 3c per lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburg, \$21.00; open hearth billets, \$21.00; San Francisco, bar, 7c to 12c per lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, ¾c per lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, ¾c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

LUMBER.—(Retail): Pine, ordinary sizes, \$24.00@25.00; extra sizes higher; redwood, \$28.00@30.00; lath, 4 feet, \$4.50@5.00; pickets, \$21.00; shingles, \$2.50 for No. 1 and \$2.25 for No. 2; shakes, \$13.50 for split and \$15.00 for sawed; rustic, \$28.00@35.00.

NAILS.—This week the basic prices are: Wire, \$2.77; Cut, \$3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, \$3.35; Cut, \$3.55; 10d to 16d, Wire, \$3.45; Cut, \$3.35; 8d, Wire, \$3.50; Cut, \$3.50; 6d and 7d, Wire, \$3.60; Cut, \$3.60; 4d and 5d, Wire, \$3.70; Cut, \$3.70; 3d, Wire, \$3.85; Cut, \$3.85; 2d, Wire, \$4.10; Cut, \$4.10. Special rates for carload lots.

LIME.—Santa Cruz, \$1.25 country, \$1.25 city per bbl.

CEMENT.—Imported, \$2.15@2.65 per bbl.; California, carload lots, \$2.10 f. o. b. at works; small lots, \$2.40 per bbl. in sacks, 4 sacks to bbl., 10c for each sack returned.

### GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 8½c; Hallett's, 8½c; San Francisco, 1000-lb. lots, 9c; 300@500-lb. 9½c; 100-lb. lots, 10½c.

OILS.—Linsed, boiled, hbl., 55c; cs., 60c; raw, hbl., 53c; cs., 54c; Lucol oil, boiled, bbl., 50c; cs., 55c; raw, hbl., 48c; cs., 53c. Kerosene—Pearl, per gal., 19c; Astral, 19c; Star, 19c; Extra Star, 22c; Eocene, 21c; Elaine, 25c; Water White, in bulk, 12½c; Mineral Seal, iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Mineral Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 16c; do., cs., 22½c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19½c; Lard Oil, E. W. S., hbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 63c; Bleached, do., 57c; Whale Oil, cs., 52@57c.

POWDER.—F. o. h. San Francisco: No. 1, 70% nitro-

glycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1\*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1\*\*, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2\*\*, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2.00 per keg.

CAPS.—3x, \$5.50@6 per 1000; 4x, \$6.50@7; 5x, \$8@8.50; Lion, \$9@9.50, in lots not less than 1000.

FUSE.—Triple tape, \$4.00 per 1000 feet; double tape, \$3.50; single tape, \$3.10; Hemp, \$2.75; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11c per set; 14 oz., 40s., 9½c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c per lb.; carloads, 23@23½c; in tins, 30c; soda ash, \$2.00 per 100 lbs.; hyposulphite of soda, 3@3½c per lb.; caustic soda, in drums, 3@3½c per lb.; Cal. s. soda, bbls., \$1.10@1.20 per 100 lbs.; sks., 90c@1.00; chlorate of potash, 12@13c; nitrate of potash, 6½@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2½@2¾c; flour sulphur, French, 2½@—c; alum, \$2.00@2.25; California refined, 1½@2c; sulphide of iron, 8c per lb.; copper sulphate, 5½@5¾c; chloride of lime, spot, \$2.50@2.75; sulphuric acid, in carboys, 66% B, 1½@2c per lb.; nitric acid, carboys, 8c per lb.

BORAX.—Concentrated, 6@7c per lb.; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

BONE ASH.—Extra No. 1, 5@6c per lb.; No. 1, 4@5c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c per lb.

MOLYBDENUM.—Best, \$2.75 per lb.

CHROMIUM.—90% and over, ½ lb., 80c.

PHOSPHORUS.—American, ½ lb., 70c.

SILVER.—Chloride, ½ oz., 90c@1.00; nitrate, 55c.

MAGNESIUM.—Pure, N. Y., \$1.60.

MANGANESE.—Per lb., \$2.75.

SODIUM.—Metal, ½ lb., 50c.

BISMUTH.—Subnitrate, ½ lb., \$2.10.

URANIUM.—Oxide, ½ lb., \$3.50.

MERCURY.—Bichloride, ½ lb., 77c.

TUNGSTEN.—Best, ½ lb., \$1.25.

FIRE BRICK.—Domestic, carloads per 1000, f. o. b., factory square, \$25.00; soap and split, \$22.50; arch and wedge, \$27.50; skewback, \$30.00; circle, \$32.00.

FIRE CLAY.—Domestic, per ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, \$3.50.

## Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s Scientific Press U. S. and Foreign Patent Agency, the following are worthy of special mention:

SAFETY GAS COCKS.—No. 779,072. Jan. 3, 1905. B. F. Clarke, San Francisco, Cal. This invention relates to a device which is designed for the prevention of accidents resulting from the escape of unburned gas. It consists of an electrical attachment for each gas cock and connections therewith by which an alarm is given at the office or other station whenever the cock stands in position to allow the gas to escape, and means by which the electrical circuit is interrupted when the escaping gas is lighted. Various arrangements may be employed by which notification can be given when a gas cock has been turned sufficiently to allow the gas to escape without being lighted, and means whereby the signal will be silenced whenever the gas is lighted. In this invention an attachment is introduced which is very effective for the desired purpose.

ROTARY FURNACE.—No. 779,119. Jan. 3, 1905. H. C. Davey, San Jose, Cal. This invention relates to improvements in roasting furnaces of that class in which a horizontal or slightly inclined cylinder is revolved upon its axis and the heat of the furnace is applied, the ore being caused to pass gradually from one end to the other. The invention consists in the combination of a plurality of revolvable inclined barrels, each having stationary heads and furnaces connecting therewith, through which heat is delivered to pass through the barrels. These barrels are set with relation to each other and provided with intermediate automatic discharge chutes from the end of one cylinder and receivers into which the ore passes and by which it is delivered to the succeeding cylinder.

GARBAGE CANS.—No. 779,051. Jan. 3, 1905. N. N. S. Matcovitch, Oakland, Cal. The object of this invention is to provide a receptacle and movable support therefor whereby the filled receptacle may be easily lifted by means of a convenient handle and made to dump its contents into the scavenger wagon without any appreciable manual labor being necessary. With a closed receptacle of this sort there is no likelihood of foul smells around a place. Being mounted as it is and so easily handled, there is an incentive to empty it oftener than if in its stead there was a heavy can to be lifted by hand, carried to the wagon and dumped in the usual unsightly and unsanitary fashion.

THE MANUFACTURE OF TORTILLAS.—No. 779,148. Jan. 3, 1905. C. H. Workman and J. Eisenbach, San Francisco, Cal. This invention relates to improvements in the manufacture of tortillas in commercial quantities, and it pertains especially to the manufacture of enchiladas—a composition of meats, peppers, sauces, spices and other things of distinctly Mexican flavor. By the use of this invention the cakes may be made very rapidly and in any desired quantity. No particularly skilled labor is necessary and the tortillas will be of uniform shape and size.

## New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, S. F., has official reports of the following U. S. patents issued to Pacific Coast inventors:

FOR WEEK ENDING JANUARY 3, 1905.

779,250.—VALVE—J. Anderson, S. F.  
779,388.—HEAVING PLUG—G. W. Barnes, Bakersfield, Cal.  
779,394.—STAMP MILL—M. P. Boss, S. F.  
779,347.—BOTTLE CORKER—W. E. Brown, Los Angeles, Cal.  
779,398.—OIL SEPARATOR—A. C. Calkins, Los Angeles, Cal.  
779,072.—SAFETY GAS COCK—B. F. Clarke, S. F.  
779,119.—FURNACE—H. C. Davey, San Jose, Cal.  
779,059.—OIL BURNER—De Remer & Robinson, Los Angeles, Cal.  
779,874.—OIL BURNER—E. B. Estly, Norman, Wash.  
779,361.—DREDGERS—R. G. Hanford, S. F.  
779,401.—TROLLEY POLE—Harrison & Fosdick, Los Angeles, Cal.  
779,967.—METAL WHEELS—J. H. Haskins, San Diego, Cal.  
779,284.—FIRE ESCAPE—Johnson & Smith, Congress, Ariz.  
779,045.—CRUSHING MILL—G. Johnston, S. F.  
779,051.—GARBAGE CAN—N. N. S. Matcovitch, Oakland, Cal.  
779,140.—TUBES—R. M. Nelson, San Diego, Cal.  
779,399.—OIL CAN—Morris & McClair, Index, Wash.  
779,306.—PANIC GUARD—J. P. Page, Portland, Or.  
779,374.—FLEXIBLE SHAFT—R. M. G. Phillips, Los Angeles, Cal.  
779,135.—ENVELOP—Louise Reinhold, S. F.  
779,898.—PUMP—W. W. Robinson, S. F.  
779,380.—BOTTLE—W. A. Statmann, Toluca, Cal.  
779,140.—TUBES—R. M. Nelson, San Diego, Cal.  
779,011.—BRAKE—Stuart & Zimmer, Puyallup, Wash.  
779,146.—TORTILLAS—Workman & Eisenbach, S. F.

## Variations in Cyaniding.

Prior to the introduction of the cyanide process in the treatment of the telluride ores of the Black Hills, little progress had been made toward a satisfactory solution of the vexed problem. It had been possible to save from 50% to 70% of the values contained in the ores by other processes, but this was generally at a cost exceeding the values extracted.

In 1899 experiments were made in wet crushing by John M. Henton, who fitted up the Dakota mill in Central City. In this mill the first experiment made in the Black Hills of crushing in cyanide solution in the mortar was tried and at once proved a success. The mill of the Dakota Co., one of those illustrated herewith, is now in the city of Deadwood. The process, briefly, consists of crushing the ore in a mortar built for double discharge, with a 0.1% cyanide solution. Four pounds of lime are added to each ton of ore to neutralize acidity. It was found that it was necessary to close some of the rear discharges, as the amount of solution with double discharge was very large. The sands are separated from the slimes by cone classifiers, each class going to separate tanks for treatment. The sands are leached with a 0.2% cyanide solution, and the slimes are treated by decantation, or overflow. The slimes being introduced to the tank from below, the solution overflows at the top. By alternate settling and syphoning off the solution is separated from the slimes and precipitation effected in the usual manner. It is stated that the cost of treatment in the Dakota mill is from \$1.25 to \$1.50 per ton, depending upon the magnitude of operations, which is not always up to the full capacity of the mill, as custom work is also done in this plant.

The Lundberg, Dorr & Wilson Cyanide Mill, Near Lead, S. D.

The other illustration is that of the Lundberg, Dorr & Wilson cyanide mill. It is at the Buxton mine, near Lead. It was here the first experiments were made by O. P. Ankeny by the bromine process in 1886. The mill has 75 tons daily capacity. It was the first mill in the Hills to use electric power; to install a Chilian mill of modern type; to employ a belt conveyor for handling materials, and to use the Moore process for slime filtration. The ore enters the mill and passes through a Gates breaker, and then to coarse rolls, which reduces it to about  $\frac{1}{4}$ -inch size. In passing through the rolls cyanide solution

is added, and the crushed ore and solution passes by launder to a Chilian mill. The pulp is lifted by a belt elevator to a classifier where a separation of sands and slimes takes place. The sands are leached and the slimes are treated by the Moore process.

It will be apparent that the processes in these two mills vary chiefly in the mechanical methods employed and not in the chemistry of the process employed. There are in Lawrence county about twenty cyanide plants in operation, including those of the Homestake, which are the largest in the world. Although there is a marked similarity in the ore treated by the various straight cyaniding mills—those in which amalgamation is not practiced, or is at least subsidiary to cyanidation, as at the Hidden Fortune mill—yet there is a notable and interesting difference in the methods of treating these highly siliceous ores. It may be assumed that the variations of the process either represent the preference of the several managers or that some peculiar physical condition in either the ore or the surroundings must be responsible for the difference. It is also apparent that the scale upon which operations are conducted is an important factor in determining the cost of treatment.

The mines in the quartzite and limestone produced last year about one-third of the total gold output of the Black Hills, the balance being derived from the veins in the Archean schists, like those of the Homestake. It is expected the Golden Reward smelter will soon be blown in, and this will probably result in a material increase in output from the mines of this class. The smelter can treat ore at almost as low a cost as that obtaining in the cyanide mills, and can also successfully treat a higher grade ore than is usual in cyaniding practice.

Mill of the Dakota Mining Co., Deadwood, S. D.

## The Limitations of Electrical Transmission.

The transmission of power by electricity has become so ordinary a thing that electrical engineers are now confidently considering what a few years ago was deemed impossible—the transmission of 100,000 volts over an electric wire. There are numerous installations carrying over 40,000 volts, and in Montana one built to transmit 80,000 volts. One of the latest schemes in Colorado is the proposal to generate electricity in western Colorado on the Grand river and transmit the energy to Denver and mines in the eastern ranges. This will be one of the most extensive installations in the West if the plans are carried out. One of the first electric installations in mining in California was that for the Standard Con. mine at Bodie, Mono county, Cal. This installation, made in 1893, was provided with a generator capable of developing under full load 3530 volts, which was a notable installation in its day. There were other plants, both in America and Europe, where the voltage greatly exceeded that at the Bodie plant; but they were relatively small as compared with the modern installations of the present day. One of the drawbacks to the successful transmission of very high voltages is the difficulty in getting satisfactory transformers which the makers are willing to guarantee. An electric company in Colorado were obliged to make an oil insulated transformer, for the reason that the manufacturers were unwilling to guarantee the transformer made by themselves. As each new undertaking in the way of expansion is successfully accomplished, the progressive engineer is willing to undertake a greater task than the last, and what may be eventually accomplished in electrical transmission can scarcely be surmised.

## Diamond Drilling in Leadville, Colo.

It was to the skillful employment of the diamond drill that the new discoveries of the past year were made in the Leadville, Colo., district. Although mining has been carried on there since 1877 in the lead-silver ore bodies, it is only within the past four or five years that the fact that the ore bodies have a distinct trend, much the same as in veins and deposits elsewhere, has attracted attention. If the ore-bearing strata of the district were undisturbed and had a uniform dip, doubtless the approach to uniformity in the distribution of the ore shoots would have been noticed soon after the development of the camp commenced; but the structural conditions are such as to have a tendency to destroy any appearance of uniformity of occurrence, which really exists. The sedimentary series was deposited in a position essentially horizontal on the floor of an ancient ocean. Later these sediments, sandstone and limestone, were intruded by eruptive rocks—porphyries of various kinds, differing in composition and, to some extent, in age. The first and larger intrusions were of laccolithic type; the later ones of lesser magnitude but of vaster importance, as related to the formation of the ore bodies. They followed the ore deposition. The sandstones became quartzites, the limestones became marble in part and were in part replaced by sulphide ores. Then occurred the faulting and uplifting of the strata into a dome-like laccolith, and the ore bodies of Leadville with their surrounding rocks were divided into a series of irregularly shaped blocks of gigantic size. The faults were not parallel, though approximately so in the greater number of instances. There are also cross faults at various angles and the entire region is thus broken up into independent blocks, the bounding planes of which have broken the continuity of the ore shoots and made a puzzling complex from the originally simple condition.

The faults vary from a few feet displacement to several thousand. To add to the perplexities of the situation, the entire district was planed off by a glacier and a lake formed, covering a large portion of the district, on the floor of which was accumulated a vast quantity of gravel. Subsequent erosion resulted in the formation of the present gulches and the exposure of the few outcrops of ore which exist in the district. In consideration of these conditions, it is not strange that the extension of the knowledge of the mineral zone beyond certain limits has been shown. In addition to the "blind" prospecting which was generally carried on through shafts or underground drifts and crosscuts, there was usually large volumes of water to contend with, and the result of the expenditure of large sums of money was often discouraging. In the early history of the camp some of the most fortunate discoveries of record were made. On Fryer hill the Little Pittsburg ore body which yielded several millions was the result of the fortuitous location of a prospector's shaft in the gravel of the glacial drift. At 30 feet from the surface a mass of iron ore, rich in horn silver, was struck, and it was subsequently proven that this was at the point of nearest approach of the ore body to the surface. A few hundred feet distant a shaft was sunk similarly in gravel on the chrysolite claim. The gravel was passed through, but in place of ore the prospector struck barren porphyry. Disgusted with his luck, the prospector salted his claim, and sold it for a few thousand dollars and decamped. The purchaser of the claim upon discovering the deceit continued his shaft 10 feet deeper, and struck a million-dollar ore body. But these things are of the past, and the miner in Leadville to-day must work systematically in his endeavor to find new ore bodies, but the results accomplished by the intelligent use of the diamond drill in the discovery of new and large ore deposits has opened up a new area of possibility in the Leadville field, and it affords a striking object lesson to miners elsewhere, who may well profit by the experience of the energetic Leadville operators.

ANOTHER suit which had been filed for damages to agricultural interests in Shasta county, Cal., in which the Mountain Copper Co. was defendant, has been tried, and resulted in a verdict of no damage, plaintiff paying the costs. The land which it had been claimed was damaged by sulphurous fumes from the reduction works was located several miles from

the smelter. During the course of the trial it was proven that the owner of the land had filed a statement with the county assessor to the effect that the fruit trees, etc., were of no value, as they never yielded any fruit. This was before the smelter was built at Keswick. It was so clearly an attempt to obtain damages where no damage had been done that the plaintiff received little sympathy. His orchard had been set out along a creek bottom where the early and late frost did much damage, usually preventing the securing of a crop. No attempt had been made at irrigation, and the land was clearly of little or no value for agricultural purposes. The soil in that portion of Shasta county is thin and impoverished at best, and the natural growth of trees is stunted and poor. Gold has been mined over the greater part of that immediate neighborhood, and during the rainy season pocket hunting is still industriously carried on by miners.

## Le Roi Seized for Taxes.

The Le Roi mine of Rossland, B. C., has been one of the concerns to attract a large share of the public attention—from the date when the mine suddenly sprung from a struggling prospector's claim to a paying proposition, valued in the market at nearly \$7,000,000, up to the more recent day of its tribulations. The latest episode in connection with this noted copper-gold mine was the seizure a few days since by the Government of its property at Rossland for non-payment of a tax of \$15,426, claimed under 2% tax on all ore mined and shipped. The original assessment was \$20,000, but the company succeeded in having this reduced to the figure stated. The property was released upon the company's furnishing a bond covering the sum demanded. The company was granted the right of appeal to the Supreme Court, but the Government demanded that the tax be paid before such appeal is taken. The refusal of the Le Roi company to comply with this demand resulted as above stated in the seizure of its property at Rossland.

The smelter at Northport, Wash., is also the property of the company. The company's defense is that they treated custom ores at Northport for which they received no credit, and that they were entitled to a further credit on the depreciation in the price of copper, which occurred during the years for which the Government is endeavoring to collect the tax. It is likely that the case will reach the Supreme Court before a settlement can be reached, and it may result in a change in the method of levying taxes on mining property in British Columbia.

MUCH attention is being given of late to the various methods of preserving timbers. These experiments are made usually on bridge timbers and those used in other open construction work and upon telephones and other poles carrying electric wires, also upon railroad ties. Little, if any, experimenting has been done on mine timbers, probably for the reason that as a rule mine timbers rarely have a chance, for what in other uses would be considered a natural life. They are warped, bent, crushed and broken and have to be replaced with greater or less frequency and have not the chance to prove how enduring preservative applications make them. Moreover, as the preserving process in many instances renders the timbers more brittle than the natural wood it might be of no advantage to treat timbers to be placed in underground workings generally, though where permanency is desired, as at stations, etc., it may be desirable to treat timbers used in such places, making ample allowance for the deterioration due to treatment. There are many places on the surface, however, about mines where it would be wise to treat timbers, with a view to increasing their usefulness and longevity, as in some mill construction, tramways, head frames, towers for the support of aerial tramways, etc., and a variety of other places.

DURING the past week there has been a sharp advance in the prices of steel and iron in Pittsburgh and throughout the East, and copper has also taken another upward movement, being quoted today at 15.5 cents. These higher prices for the leading and most largely consumed metals in the industrial world augur well for the new year. The metal market is an almost infallible index of the condition of industrial life the world over.

## CONCENTRATES.

SILICATE OF SODA and powdered glass or silica (quartz) forms an excellent lute for cementing the covers onto crucibles, etc.

THE various kinds of cement on the market weigh dry from fifty-six to ninety pounds per cubic foot. Granite will weigh about 170 pounds per cubic foot.

TABLES showing the amount of water that can be delivered through pipes of given diameter under varying heads can be found in most engineering books and works devoted to hydraulics.

THE loss of gold in the cyanide tanks by absorption is without doubt a small factor in the losses, which must be looked for elsewhere. Perhaps the fault lies in the precipitation boxes, or in refining the precipitate.

CHYSOTILE is a silky, fibrous variety of serpentine, resembling asbestos. Chrysolite is another name for olivine, a mineral occurring in grains in a number of basic rocks like basalt, diabase, uorite, etc.

THE water pressure per square inch under 500 feet head is 216.5 pounds, and the spouting velocity is estimated at 10,759.96 feet per minute. The estimated power for each miner's inch—1.5 cubic foot per minute—is 1.2 H. P.

IN the construction of towers for aerial tramways, wind stresses as well as direct weight of the load to be carried must be taken into consideration, and where towers cannot be readily braced they should be guyed or anchored to the ground.

WHERE rubber gaskets are used in contact with iron surfaces, it is a wise precaution to rub the surfaces of both rubber and iron with graphite before placing the gasket in position, as it will greatly facilitate its renewal, which will ultimately become necessary.

SOME VARIETIES of crude oil can be used in gas engines. Both in Nevada and in California, Coalinga oil has been successfully used, in preference to gasoline, or distillate, in the gas engine, for hoisting, running pumps, mills, etc. The very heavy oils are not suitable for this purpose.

LEAKS in pipe lines are sometimes stopped, temporarily, at least, by throwing sawdust into the box at the head of the line. This is carried into the pipe and more or less of it finds its way to the leaks, and clogging the small aperture stops the leak. In some cases this simple remedy fails of satisfactory results.

THE legalized miner's inch in Montana and California is 1.5 cubic foot per minute. As this establishes a standard of measurement, it is being generally adopted in other States, as it avoids the confusion created by the varying head under which water has been measured by various water companies.

THE general belief is that copper plates, whether silver plated or not, absorb gold when used for a long period for amalgamating gold in the mill. There are those who contend that this is not a fact, and that if a plate be thoroughly scraped down to bright copper, no more gold can be obtained by scraping, sweating or even by the fire assay.

THE greatest annual production of gold and silver in the United States, according to the Mineral Resources of the United States for 1903, was in 1901, when it reached \$153,704,495. Of this amount \$79,171,000 was in gold. The gold production of 1902 was \$80,000,000. The largest amount of silver produced in one year was in 1892, when it was \$82,101,000 (coinage value).

A GOOD CEMENT for iron may be made in the following manner: Clean, fresh iron filings, 40 parts; manganese dioxide, pulverized, 10 parts; sal ammoniac, 1 part; Portland cement, 20 to 40 parts. Add water to form a paste. Flower of sulphur may be substituted for the manganese dioxide. When this mixture is made galvanic action causes rapid oxidation of the iron, the volume swells somewhat and the mass forms a firm cement.

IT is thought by many mill men that the continued and often heavy vibration caused by falling stamps is detrimental to the best results in amalgamation. That this is probably a mistaken idea is suggested by the successful use of "bumping" amalgamation tables, and the recent substitution of silvered-copper plates on old vanners in a mill on the sand where the shaking and great vibration of the plate has resulted in catching a large amount of free gold which would otherwise have gone with the pulp to the cyanide works.

IT is customary to do all mine surveying with a fixed needle and a vernier, owing to the magnetic attraction found in mines, due to the presence of tracks, drills and other tools. Some rocks contain a sufficient percentage of magnetite or pyrrhotite to deflect the needle several

degrees. When surveying with a needle on the surface the surveyor should be careful to remove all iron and steel objects from the person, such as keys, knives, buttons, buckles, etc. On one occasion the writer set up a compass on a mine and left it for several minutes for some purpose. On returning the needle had come to a state of absolute rest, but upon approaching near enough to read the plate the needle was deflected 4° by iron and steel objects in the pockets. Needle surveying is only approximate in accuracy at best.

PRODUCER GAS is made from any kind of fuel. In small-sized plants anthracite coal, coke or charcoal is preferred, though wood may be used. The gas is made in a device called a producer, of which there are several makes. It is claimed that producer gas is the cheapest form of energy from fuel. Its calorific value is about 140 B. T. U. per cubic foot of gas. It is made by passing steam through a bed of incandescent coals in a closed producer. The fuel is converted into fixed gases and only ash remains. It is used for power, fuel, heating, etc. Its use is extending.

THE velocity of a stream is not equal throughout its entire depth. Recent extensive experiments made by hydrographic engineers of the United States Geological Survey determine the mean velocity to be at a point from 58% to 73% of the depth of the stream; depending upon the character of the bed, whether rough or smooth. The mean depth is 61%. The United States engineers have adopted six-tenths of the depth of the stream as the point of mean velocity, and experiments carefully made show this to be about correct, the variation being from -6% to +4%, with a mean of 0%.

WATER is lifted by the hydraulic ejector and also by compressed air. In each case the method of operating is essentially the same. The water or air is carried down under the surface of the water to be lifted, and the pipe there reduced in size to a nozzle-like termination is turned upward into the lower end of the column pipe. The great upward force of the water, in its effort to seek its own level—the pressure head—carries with it by suction a quantity of water from the body of water in which it is immersed. The water rises steadily in a solid column and is discharged. The efficiency of the hydraulic elevator is relatively low. In the air-lift the air enters the lower end of the column pipe and beneath the surface of the water and forces a quantity of water upward in the pipe. The water is carried upward in a series of detached sections, with an air space or cushion between them, making the discharge intermittent.

WHERE A locates a claim on a vein, and subsequently B locates one adjoining, the vein running with a sinuous course along A's side line, crossing and recrossing the line, but dipping away from A's claim, B has an extralateral right on that segment wholly within his own claim where the discovery was made, but that he may have the same right on the several other segments lying within his claim without making a discovery for each separate segment is a question. There appears to be no precedent for such a case and it might be necessary to carry the question to the Supreme Court of the United States to get a final decision. A is entitled to all the lodes or veins found within his claim and is entitled to the extralateral right on each of the several veins or portions of veins having their apices within his lines. It would seem that B might have a similar right, but the question is, as previously stated, without precedent. As to a cross lode, B has no right within the lines of A's claim for any purpose, in either Arizona or California, according to court decisions.

AN EXTENSIVE list of minerals occurring in California was published by Henry G. Hanks in the fourth annual report of the State Mineralogist of that State in 1884. This list referred more particularly to those minerals of economic importance. Tellurium-bearing ores are found in a number of localities in California. Among these are altaite, telluride of lead, at the Rawhide mine, Tuolumne county; calaverite, a gold and silver telluride in Calaveras and Tuolumne counties; hessite, a silver telluride, found in a mine near Georgetown, El Dorado county; petzite is a variety of hessite, the silver tellurium. It has been found in the Stanislaus mine of the Melones Co. at Robinsons in Calaveras county. Sylvanite, a complex telluride of gold, silver, antimony and lead. This is also found in the Stanislaus and Melones mines. Native tellurium and the rare telluride of nickel, melonite, have been found in the Melones mine. There are other tellurium minerals reported from the interesting groups of mines near Carson Hill, but their identity seems doubtful.

A PERCH of stone is 16½x14x1 feet and contains 24½ cubic feet. A good concrete is made in the following proportions: Clean, broken rocks, 4 parts; sand, 2 parts; cement, 1 part. To make a perch of concrete, take 2500 pounds broken stone; add 1250 pounds sand and 625 pounds cement. The addition of sand and cement does not increase the bulk of the concrete. This is determined by the amount of broken rock employed. The sand, cement and water merely fill the voids or spaces between the pieces of broken rock. Consequently, when the quantity of concrete is known in cubic feet, the amount of the several ingredients may be calculated closely. The proportions are as 1:2:4 for cement, sand and

rock, and 1:2:4:8 for cement, sand, gravel and rock. Someone has said that, when getting the stone for a mass of concrete, "get all the stone that in your judgment is required—and then get as much more." It is not of infrequent occurrence that inexperienced concrete makers underestimate the quantity of stone required. Slow-setting cements are best for concrete, particularly for those that are to be rammed.

A DIRECTOR and stockholder of a mining corporation, who has served also as superintendent at the instance and request of the corporation, is entitled to be paid for his services as superintendent. The salary of superintendent is usually fixed by the by-laws; but, in the absence of that, if there has been an express agreement upon the amount he was to get, by a valid resolution of the board of directors, wherein his own vote was not necessary to carry the resolution through, the corporation will usually be bound thereby. If there has been no express agreement, he will be entitled to the amount his services as superintendent were reasonably worth. His being a director has the effect in some cases of limiting the amount he can demand as to what his services were reasonably worth, even though there was an express agreement fixing his salary at a larger sum, but it does not otherwise affect his position as a creditor of the company. He may enforce his claim for services in the same way as other creditors, by suit and attachment, or, if his superintendency involved active physical labor, by filing a lien under the mechanics' lien law.

ZINC is not in evidence in the upper portions of some veins where it was originally a portion of the ore deposited there. There are two theories which are advanced to account for the fact that some mines which show little or no zinc near the surface sometimes develop the sulphide of that mineral in considerable amount in depth. One is that zinc sulphide is one of the first minerals to be precipitated in veins from its mineral solutions coming from depth. The other is that the zinc was originally precipitated together with other base metal sulphides, but that subsequent decomposition resulted in the oxidation of the zinc sulphide to zinc sulphate which, being soluble, was carried away by downward percolating surface waters, and consequently little or no zinc mineral is seen in the upper levels, where zinc blende may prove to be an important constituent of the vein below the drainage water level of the mine. In some instances zinc silicate or zinc carbonate are abundantly deposited in an intermediate zone as a result of the alteration of the surface ores by oxidation, but as often the carbonate and silicate are absent or exist in so small amount as to attract no attention.

THE hardening of steel is due to suddenly arresting the progress of a change which otherwise takes place in the condition of the steel when slowly passing from a higher to a lower temperature. The metal having been completely and suddenly cooled, no further change can take place. This is accomplished by plunging the red hot steel into water. In the case of a pick, the steel point is burnished by the blacksmith—generally by rubbing on a board covered with sand. This brightens the surface of the steel. The shank of the pick still retains a high heat, sufficient to carry it down to the point. Watching it closely, a beautiful dark blue color is soon seen. Just at the moment this reaches the end of the pick point, it should be given the final plunge, and the point will retain this color, dark blue, and is the best for hard rock, as well as that which is softer. Drills may be tempered in much the same way. Usually drills are heated and forged and thrown down to cool, being afterward reheated, plunged and tempered by allowing the color to run down to the bit, but drills for hard rock should be tempered from straw to light bronze color, blue being too soft. In heating to forge or to temper, care must be taken not to overheat the steel, as this burns out the carbon and ruins the steel for any use and the burned end must be cut off and thrown away, causing a loss of fuel, time and material.

SODIUM AMALGAM is composed of sodium and mercury. It is made in a quicksilver flask from 3 parts of sodium and 97 parts mercury. Bury the flask in a sand bath on the furnace, nearly up to the neck of the flask. This is brought to a temperature of 300° F. Place the mercury in the flask first and then add the sodium in small pieces—the size of a pea—waiting each time until the violent action stops before adding another piece. It is better to handle the sodium with tongs and protect the hand with a cloth or glove, as the addition of each piece of sodium is followed by a slight explosion and a jet of flame issues from the flask. The action becomes less pronounced as sodium is added. When all of the sodium has been added, pour while still liquid into a flat dish. The mass will solidify when cold and may be broken into small pieces and placed in a stoppered jar. Sodium amalgam forms in bright, metallic needle-like crystals, which interlace in every direction but are loosely coherent. The amalgam thus prepared is used by pulverizing to a coarse powder, and sprinkling over the surface to be amalgamated, which is previously wetted, and then going over it with clean mercury. The result is a perfectly amalgamated surface, but in case of bad plates it may be necessary to repeat this a number of times, until a good layer of gold amalgam has been formed on the plates. This can only be possible by not removing the gold as fast as it is deposited—a too common practice.

## The Mines of Cripple Creek, Colo.

The recently completed resurvey of the Cripple Creek, Colo., district has resulted in the securing of considerable additional valuable information. There are about 300 mines in the district, some of which are idle; numerous others have been consolidated into groups, which have become familiar by name to mining men everywhere. The deepest mine in the district, measured from the collar of the shaft, is the Lillie, down 1500 feet.

The width of veins stopped ranges from 3 to 50 feet or more. The stopes are sometimes filled, but are often left open after the broken rock between levels has been drawn off. Operations are facilitated by the great hardness of the rock, stopes 200 feet or more in height sometimes standing for years. The ores are not adapted to concentrating by ordinary means. Hand sorting and washing, the latter in order to separate the fines, are the methods employed. More care is now taken than formerly, but at many places there is still room for improvement.

The recently issued bulletin No. 254, by Lindgren and Ransome of the United States Geological Survey, gives the following resume of the mines of the district:

**BRIEF REVIEW OF THE MINES.**—The productive district, as stated above, is practically covered by the area of a circle  $3\frac{1}{2}$  miles in diameter. The center of this circle would be located half way between Raven hill and Bull hill, and the towns of Cripple Creek, Victor and Cameron would be situated on its periphery. A very few mines—notably the Galena and the Fluorine—and many prospects lie outside of this area.

The culminating points of the district are found in a ridge of high and bare hills that extends in a northwest-southeast direction and divides the waters flowing into Cripple creek and Wilson creek on the southwest from those joining Spring creek and Grassy creek on the north. From northwest to southeast the following hills mark this divide: Mineral hill, Carbonate hill and Tenderfoot hill, north or northeast of Cripple Creek; Globe hill, Ironclad hill and Bull hill, the latter being near the center of the district and equidistant from Cripple Creek and Victor; the ridge is continued by Bull Cliff and Big Bull mountain, the latter, really outside of the productive area, being the highest point in this dividing range of hills. Its elevation is 10,826 feet. Three long spurs project to the southwest from the dividing range separating the deep trenches of Cripple creek, Squaw gulch, Arequa gulch and Wilson creek. The first, called Gold hill, rises directly east of Cripple Creek; the second is Raven hill, being continued to the southwest by the lower spur of Guyot and Beacon hills; the third is Battle mountain, continued by the almost equally high salient of Squaw mountain.

The important mines are situated in this region of sharply accentuated topography. As has been several times emphasized, the volcanic area practically coincides with the hills and ridges just described and is surrounded on all sides by granitic rocks.

Globe and Ironclad hills and Gold and Raven hills consist chiefly of heavy masses of breccia and were scenes of great activity during the early years of the district. Near Poverty gulch, just northeast of Cripple Creek, is the Abe Lincoln, not a large mine, but still actively worked with satisfactory results. Higher up are the Gold King, with dividend records of \$150,000, and the C. O. D., with a reported production of \$600,000 and dividends of \$150,000.

On the summit of Globe hill are the Stratton properties of Plymouth Rock and Globe mines, in which extensive low-grade mineralization without many sharply defined veins seems to be the rule. Adjoining is the property of the Homestake Co., including the Ironclad mine, where direct cyaniding of oxidized surface ores is now carried on in a mill erected on the property.

Gold Hill is crowned by the Anchoria-Leland mine, with a production of over \$1,000,000. The shaft is 1100 feet deep. The adjoining Moon-Anchor has paid dividends of \$261,000, and the Half Moon (Matoa G. M. Co.) has a gross production of \$650,000 to its credit, but is reported to have paid only a small amount in dividends.

On the western slope is the Midget mine, actively worked at present, with a depth of 800 feet, a total production of \$662,000. The Conundrum, in the same vicinity, is likewise worked with good results to a depth of 600 feet. The Midget, like the mines described above, follows a vein in breccia, while the Conundrum is mining on a basalt dike in granite, close to the contact of the breccia.

In the deep gulch between Gold hill and Raven hill are situated the Anaconda, Doctor-Jack Pot and Mary McKinney mines, all working on sheeted zones forming lodges in the breccia. The Anaconda produced about \$1,000,000, chiefly from upper levels, and is now idle. The Mary McKinney is one of the most successful mines worked at present in the district. Its depth is 600 feet. The Doctor-Jack Pot has \$4,000,000 to its credit and likewise a handsome dividend record. The shaft is only 700 feet deep, water having until now prohibited deeper sinking.

The breccia granite contact is found on Guyot hill a

short distance south of the Mary McKinney. The extreme spur of Raven hill, called Beacon hill, is formed of an intrusion of phonolite in granite, and about this outlying volcanic center cluster a group of veins of great production and promise. On the eastern side of the hill are located the Prince Albert, Gold Dollar and others, not active producers at present, while on the western side lie the El Paso, C. K. & N. and Old Gold mines, with their narrow but extremely rich fissure veins in granite, now actively and successfully worked.

A great number of smaller mines have been worked on veins cutting the breccia of Raven hill. The Elkton mine is situated in the deep hollow between Raven hill and Battle mountain. It has been working on an exceptionally long vein, partly contained in breccia, partly in granite, and generally following a basalt dike. The production approaches \$6,000,000 and the depth attained is about 900 feet, excessive water having formed a serious obstacle to deeper sinking. The Moose mine, situated higher up on the slope of Raven hill, had a good ore shoot, from which \$500,000 was obtained.

Northwest is the summit of Bull hill, which affords a magnificent panorama, not only of the whole camp, but of a large part of the State of Colorado. Toward the east, and 5000 feet lower, spread the great plains at the foot of the Rocky mountains; westward the Sangre de Cristo, Collegiate and Mosquito ranges—a snowy and jagged line of ramparts—define the distant horizon.

A multitude of small mines occupy the southwestern slope of Bull hill. On the northwestern side an area of brecciated granite appears among the volcanic rocks, and in this formation is situated the Wild Horse mine. This lode, which has been worked to a depth of 1250 feet, has produced over \$1,000,000, and is now operated by lessees. A number of smaller producers may be found on the northern slope toward Cameron, among them the Damon, Jerry Johnson, W. P. H. and Pinnacle.

The mines are chiefly situated on the periphery of a circular area, the central part of which, comprising the upper part of Squaw gulch, has thus far yielded very little. Few strong veins have been met with in this part of the breccia; but, on the other hand, the developments in depth are not extensive.

On the east and southeast side of Bull hill begins that most important belt of lodges which extends southward to Victor and includes the richest group of producers in the camp. A characteristic feature of this belt is the intrusion into the breccia of thick masses of trachytic phonolite and syenitic rocks.

With few exceptions the veins of this belt strike north-northwest. We may begin the description with the system of linked veins, 3000 feet long, covered by the Isabella and Victor mines. The last-named mine, on the southern end of the system, is situated just below the western slope of Bull Cliff. It has been worked to a depth of over 1000 feet and has produced about \$2,200,000. The Isabella has attained a depth of 1127 feet and produced \$3,200,000. Both mines lost their pay shoot in depth.

The small but rich cross veins of the Empire State, Burns, Pharmacist and Zenobia connect this vein system with that of the Stratton mines on Bull hill. South of the Burns begins the Vindicator vein system, traced southeasterly for a mile through the Findley, Hull City, Vindicator, Lillie and Golden Cycle mines. The Hull City and the Lillie have each produced over \$1,000,000, the Vindicator and Golden Cycle over \$2,000,000 each. The Vindicator is 1200 feet deep. All of them, except the Lillie, are still actively worked. In the whole system water has been and is still a source of trouble. The deepest mine evidently drains all the others in this vicinity.

The Stratton properties on Bull hill, with the Logan, Orpha May and Pikes Peak veins, on which maximum depths of 1200 and 1500 feet have been attained, are now worked only to a slight extent, whereas in the early days of the camp they were highly productive.

This vein system is continued southward in the Last Dollar mine, now working at a depth of 1270 feet. The production exceeds \$1,000,000. South of the Last Dollar the veins enter the Modoc ground, a mine worked for a long time and with gratifying success. The Blue Bird, an old-time producer, is situated a short distance west of the Last Dollar.

South of the Modoc is the Battle mountain vein system, crossing from the granite into the breccia, with general northerly or north-northwesterly directions, and distinguished by heavy production and ore bodies of imposing size. None of the veins are of great length, and the whole system extends scarcely a mile along the strike of the veins. The veins can not be directly connected with others already described, though, in its general trend, the system heads toward the Dexter, Blue Bird and Moose veins.

Beginning on the southwestern side, we first come to the Gold Coin mine, the veins of which are in granite; one of them is successfully worked at present at a depth of 1200 feet. The total production approaches \$6,000,000. North of the Gold Coin is the Ajax, working partly in veins, partly in large, irregular ore bodies in the granite. The depth attained is 1200 feet.

Between this and the Portland vein system, almost within the town of Victor, are the Granite, Dillon and

Dead Pine veins. They are worked at present at depths of from 800 to 1000 feet.

The Portland vein system begins on the south at the Strong mine, now worked at a maximum depth of 900 feet, on a vein in granite that follows a basalt dike, which is in places accompanied by a phonolite dike. The mine is an unusually regular and profitable producer, the total dividends since 1892 amounting to \$2,500,000.

The veins of Stratton's Independence run about parallel to those of the Strong, a few hundred feet eastward. They extend from the granite into the breccia, following for some distance a phonolite dike. The production of this mine amounts to over \$11,000,000. At present the company is leasing the various levels to tributaries. From the two properties last described the vein systems continue into the Portland mine, but in the northern part of the property are replaced by another and still richer aggregate of veins, the Captain system. The Portland is, beyond question, the most prominent mine of the Cripple Creek district. Its total production from 1894 to the end of 1903 amounted to \$18,000,000, derived from 466,000 tons of ore (both in round figures).

**OUTSIDE MINING PROPERTIES.**—The area outside of the principal volcanic area contains very few productive properties, but it is by no means barren. A great deal of money has been spent here, usually with unsatisfactory results. Although there are many properties of merit, and although much honest effort has been made in this part of the district, it has long been the favorite camping ground of concerns more or less lacking in stability.

The granite hills west and south of the city of Cripple Creek contain few prospects; phonolite dikes occur in places, but usually show little value. Along Gold Run and Arequa gulch prospects with a little ore have been found, down to the junction with Cripple creek, and even at isolated places below this locality. Grouse mountain, with its phonolite cap, shows many prospects from which occasional good assays have been obtained; but neither here nor on Straub and Brind mountains has anything of permanent value been developed thus far. It is claimed that ore bodies of low grade, containing a few dollars per ton, exist.

The breccia caps of Mineral, Carbonate and Tenderfoot hills are dotted with prospect dumps, and even shafts several hundred feet deep. Nothing of permanent value is recorded from Mineral hill, though fairly productive placers have been worked at its southwestern base, almost in the town of Cripple Creek.

On Carbonate hill the Elkhorn has been a small producer; on Tenderfoot hill the Friday, Hoosier, Black Diamond and Mollie Kathleen contribute their parts to the production. Two miles north-northwest of Cripple Creek is the Galena mine, the vein of which follows for a part of its course a phonolite dike in granite and has a small output to its credit. About the same distance north of the city is the small volcanic center of Copper and Rhyolite mountains. At the former the Fluorine has produced \$160,000 and low-grade ore is now being cyanided. Prospects are found on Rhyolite mountain, and, in fact, all over the granite country between it and Trachyte mountain. The Lincoln mine, near Gillette, and several other prospects farther south, along a belt of phonolite dikes, have produced a little ore. It is claimed that there are low-grade veins on both sides of Bernard creek, northwest of Gillette, in a region of granite with occasional dikes and masses of phonolite. Trachyte mountain, southeast of Gillette, is covered by phonolite, and a little ore is occasionally found in veins at its southern foot. Some work has also been done on Cow mountain, about 4 miles northeast of Bull hill.

**CHARACTER OF THE ORES.**—The characteristic feature of Cripple Creek ores is the occurrence of the gold in combination with tellurium, chiefly as calaverite, but partly also as the more argentiferous sylvanite, and probably, to a minor extent, as other gold, silver and lead tellurides. The tellurides are frequently associated with auriferous and highly argentiferous tetrahedrite, with molybdenite, and occasionally with stibnite. While these minerals have not yet been closely studied, preliminary examination indicates that their contents in gold are due to an intimate mechanical mixture of tellurides. Pyrite, while widely disseminated through the country rock and of common occurrence in the fissures, is rarely sufficiently auriferous to constitute ore. Such of the pyritic ores as have been tested reveal the presence of tellurium, indicating the ore is a mixture of pyrite and gold-silver tellurides. Galena and sphalerite occur in small quantities in many of the mines, but rarely contain enough of the precious metals to form ore. Native gold appears to be absent from the telluride ores, except as it may be set free by the oxidation of these tellurides.

The usual gangue minerals of the ores are quartz, fluorite and dolomite. Roscoelite and rhodochrosite are also found in places. Celestite, or sulphate of strontium, while never present in large amount, frequently occurs as little acicular crystals in the quartz vugs of the lodges. Calcite occurs interstitially in much of the breccia near the ore bodies, but is rarely found in distinct crystalline form with the ore minerals. Secondary potassium feldspar is common in

the ores; it is especially abundant in the ores enclosed in granite, particularly those in the Pikes Peak type. This feldspar has the composition of orthoclase, or microcline, and is formed by the recrystallization of the original potassic feldspar contained in the rocks. In the granitic ores of the Stratton's Independence, Portland, Ajax and Elktou mines this secondary feldspar is the principal gangue mineral.

Oxidized ores, while still worked in many properties, are of relatively less importance than when Penrose described the district. The deep workings of the present day show that kaolin is always connected with oxidation and is not a product of the original mineralization of the district, as was supposed by Penrose.

The Cripple Creek ores, as a rule, contain very little silver, the average proportion being about one ounce of silver to ten ounces of gold. In the Portland and Stratton's Independence mines the proportion is very much less, the silver from the Portland in 1901 amounting to only 2.4 ounces for each 100 ounces of gold.

The average value of the Cripple Creek ores lies probably between \$30 and \$40 per ton. In some of the larger mines the average value sinks to about \$25 per ton. From a lower economic limit of about \$12 per ton the values of individual shipments swing through a wide range up to ores carrying \$3000 or \$4000, or even \$8000, per ton. Occasionally smaller amounts—one or two tons—have yielded as much as \$50,000 per ton.

(TO BE CONTINUED.)

### New Mill at Poland, Ariz.

The Poland-American G. M. Co. have started their 100-ton mill at Poland, Ariz. This will work the ores of the Vassar, Fitzhugh Lee and Joe Wheeler claims, which produce a hard ore and a soft ore requiring different treatment. The hard ore is crushed with

stamps, the free gold caught on amalgamating plates and the sulphurets saved on Wilfleys and vanners. The soft ore is crushed with Colorado Iron Works rolls and then passed over Wilfleys and vanners into the drying rooms. C. J. George of Los Angeles, Cal., is president and general manager.

### Cinnabar in Arizona.

Recently the discovery of cinnabar, the sulphide of mercury, at Copper Basin, Arizona, has been announced in press dispatches. Cinnabar was discovered in some mining claims located 2 miles southwest of Copper Basin in 1890, and it is more than probable that the recent reported discovery is of the same occurrence. The original discovery was made by a man named McNeary, who lived near these claims. The occurrence is of more than ordinary interest, owing to the mineralogical association of the cinnabar.

It occurs in rhyolite, accompanying large pseudomorph crystals of hematite, after pyrite, an unusual occurrence of cinnabar. Evidently there was at one time a deposition of iron sulphide along a zone of fracture in the rhyolite, some of the sulphide assuming the form of groups of cubes up to an inch in diameter. These groups of pyritic cubes occurred in vug-like spaces or cavities, and were attached to the rhyolite walls of the cavity. Whether the cinnabar was deposited simultaneously with the pyrite or not is not apparent, but it now occurs mostly about the base of the groups of pyrite crystals, which have been completely altered to hematite, though still retaining the form of the original pyrite. Quartz and iron oxide and hematite are abundant in the zone of fracture, though the cinnabar occurs in relatively small amount. It was claimed the iron oxide contained gold, but as to this the writer is uncertain.

### Ancient Spanish Mine Workings.

Jos. McGillivray, the veteran hydraulic miner from Dawson, Y. T., who is spending the winter in California, tells of his experience some years ago near Astorga, Spain, where he had gone as consulting engineer for the Rothschilds, who were exploiting some placer ground in that region. Mr. McGillivray found that the gold gravel had been worked by the Romans when Iberia was a Roman province, centuries before the Christian era, and remains and traces of the ancient workings could be distinctly seen. With no knowledge of modern mining methods, in a country destitute of timber and dependent on slave labor, the work was necessarily crude; yet Pliny, the historian, records the annual production of 20,000 pounds of fine gold from those gold mines near Astorga under the Roman sway. The course of an ancient ditch 30 miles in length can be traced, and rock supports, in lieu of timbers, are still discernible. For "flumes" they cut channels in the slate and for "rifles" therein used a sort of heather, which was afterward collected and burned, the gold being as a residue in the ashes.

Mr. McGillivray found where an area of 10,000 acres had been worked over. A curious feature was the evident practice of a custom that, so far as hitherto supposed, originated at Canon Creek, Trinity county, Cal., viz., "booming." That unique form of using water in hydraulic mining is a way of making what would ordinarily be an insufficient flow of water do quick but not lasting work. The arrangement consists of an automatic reservoir of various sizes and shapes that collects all the water not run through the giants or monitors for, say, fifteen minutes, and then a valve automatically opens of sufficient size to allow all the water thus collected to escape in five minutes, thus obtaining the use of over 20,000 inches of water for five minutes that 2000 inches has furnished by caching it for fifteen minutes. That force of water will carry boulders weighing over 500 pounds through 1 mile of flume in five minutes. On the Boss & McClary placer mine, adjoining Trinity Center, Cal., the "shooter" box is 20x40x6 feet, with an automatic opening of 18 inches by 4 feet. They have a bedrock flume, 6 feet wide by 3 feet deep, nearly half a mile long, lined with 9-inch blocks.

It was in northern California that that style of hydraulic mining was supposed to have been first introduced, though something similar in operation was evidently used in the old days of ancient Rome. It is usually practiced only along California gulches. These affording little water, it became necessary that the limited supply be reservoired and properly distributed in order to make it effective in this method of gravel washing. The object is attained by retaining the water in dams and then releasing it suddenly, with a rush or boom. Near the bottom of the dam built for this purpose is left an aperture so large that, when opened, the water escapes rapidly. Placed on the top of the structure is a small race, through which the water flows when the dam is full, and is discharged into a large wooden box suspended from the end of the sweep, turning on a pivot, and the upper end of which extends to and over the top of the dam. Attached to this end of the sweep is a strip of heavy canvas, which, dropping in a fold over the aperture below, keeps it tightly closed when the dam is full. When this stage has been reached, the water flowing through the race into the wooden box mentioned soon fills it, causing this end of the sweep to sink and the other to rise, carrying with it the strip of canvas and uncovering the large aperture below, allowing the water to rush out. Meantime, the wooden box, having emptied itself through numerous small bores made for the purpose, this end of the sweep, relieved of its weight, rises and the other end drops. The canvas falls over the outletting aperture, closing it as before. Then the dam fills again to the brim and the operation as above is repeated. This plan for handling water is wholly automatic. It takes care of itself and goes on day and night, without any attention on the part of the miner, doing its work as long as the water lasts.

Some of the miners call it a "self-shooter." What term was applied to it by the old Roman miners Mr. McGillivray was unable to say.

### The Extralateral Right Law.

TO THE EDITOR:—Will Mr. John Stewart permit me to take issue with some of his remarks on the extralateral right law in your issue of December 31?

It is purely theory when Mr. Stewart says: "It is breaking of this law, 'Thou shalt not steal'—ore from your neighbor's claim—and not the just provision of the extralateral right that is at fault." A logical (?) argument indeed to say that!

If Mr. Stewart has seen many extralateral right lawsuits he has seen litigants on each side conscientious in belief that they have the apex; if Mr. S. has been underground he certainly must admit that he has been puzzled as to which outfit has the apex. This discovery before location is all very pretty but not always practicable.

Take Creede, Colo., when staked on the snow; this great camp covered with wash and no outcrop; claims piled about as though you threw packs of cards on a table. I hear Mr. Stewart say from his armchair, "Such locations are illegal, invalid, etc."

That's true. We know that. But let any man come in during a mining excitement and say that, or attempt to dispossess a man of title so founded. It means "bucking" the community. With development and patents, veins run "any old way" as regards claims; then come your extralateral right suits.

"If, if—" and then talk how claims ought to be located, is theory and does not remedy a condition. The extralateral right claim statute was passed when claims with outcrops were the rule. It is truly absurd, as any miner knows, to always tell easily which has the apex.

Does Mr. Stewart imagine any company would employ experts, the best legal talent, have maps and models made, and enter a contest that costs many thousands of dollars, if they knew they were wrong—would lose the suit, and their money; and have costs put on them, when all they have to do, according to Mr. Stewart, is to murmur "Thou shalt not steal" to their opponents and "We are right." Fudge! With equal honesty, the other side spends money for battle and says, "It is our ore, not yours." Then the fight is on for the apex that each chap, under this wonderful statute, thinks he owns.

"In course of every few years it has become fashionable for some ambitious lawyer or mining engineer to make the grand discovery, as did E. A. Belcher, that the extralateral right should be abolished," so Mr. Stewart tells us. Does he know a U. S. commission investigated this question almost thirty years ago and published a heavy report of investigations in camps, of litigation and of many eminent men and cost of useless litigation and recommended changes. It was a mighty able commission, Mr. Stewart, so do not throw stones at its becoming fashionable now by Mr. Belcher.

"There are more theories in this world, Horatio, than are dreamed of in your philosophy."

"The square location is also undesirable on account of its covering more leads or deposits than the vein or deposit which is subject of location."—Stewart.

Suppose it does. Does not many a mining claim now; does not a group of mining claims now, that one man may own?

"As a consequence, prospecting is prevented, or good mining ground is tied up, etc."—Stewart.

Is it tied up more than when patented, or where annual work is done? Certainly not.

"Hence it is that where the square location exists little prospecting and mining are done. It therefore stops industry in mining, and as industry is the secret of happiness among civilized people it is not a law nor condition which is for best interests."—Stewart.

Now from far and near, fellow miners, would not that medley of statements and morals at finish jar you?

For the first part of it, Mr. Stewart, how about Mexico and Australia? Some mining there, is there not? Production seems to indicate it. "Square" locations too; this location, which you say is a good farmers' boundary, prevails in Mexico and some other countries.

I mean it courteously when I say I question Mr. Stewart's ever having fought an apex suit or been a witness on one, nor having witnessed in person the staking of a new camp where there are no outcrops.

His idea of arbitration on the ground is very pretty. It could be done on surface boundaries, but if this beneficent act is so clear that "Thou shalt not steal" is the head and front of it, my dear Mr. Stewart, why the disputes ever, and need of your arbitration?

"Those who desire a change in the law as at present have good intentions, but they base their arguments on wrong premises."—Stewart.

I am grateful that we have "good intentions." The rest of the paragraph is merely a calm, self-satisfied statement, but no proof.

All Mr. Stewart's arguments smell of the lamp, of theory. The syllogisms are of college, of class room. The wielder of the pick, the carrier of the

transit, the prospector, the miner, who has been, who has seen, who is, seems absent.

"An experience of forty years' mining \* \* \* enables me to give facts on this important question for protecting the best interests of capital and labor invested in mining."—Stewart.

Methuselah was not the wisest man, I am sure, and we await facts. The extralateral right law is an ideality, a dream, but it certainly is not in its application. Thank Mr. Stewart for permitting my discussion.

RICHARD ROELOFS.

Cripple Creek, Colo., Jan. 14.

## Cyaniding Raw Pyrite.

TO THE EDITOR:—In "Concentrates" of December 24, 1904, appears a statement to the effect that the successful treatment of auriferous pyrites by direct cyanidation is dependent upon fine grinding; and that a material almost in the condition of slimes is necessary for the possibility of high extraction. This, however, is only partly true, for while fine grinding is very desirable in the treatment of raw sulphides by cyanide, it is not absolutely necessary, the factors, time of treatment and depth of charge, having been found in actual work to be of far more importance.

At a small plant installed some years ago by Wallace Macgregor near Johnsville, California, several thousand tons of fairly clean sulphide concentrates were successfully treated in the raw state by cyanidation. The material was in very widely different degrees of fineness owing to the use of different sized screens at different periods in the mill where the concentrates were produced, and also to the fact that a considerable part had been reground in amalgamating pans, with a partial recovery of gold as base bullion, to a fineness approaching that of slimes. The coarser material, which was mostly of a size similar to that produced in a stamp mill where ordinary 30-mesh slotted screens are in use, had been in part lying on the dump for several years, though still bright and containing no salts, while another portion had been but very recently mined by leasers. The finer product was for the most part badly weathered and introduced a problem in the matter of washing out the soluble sulphates, which came away with the first wash waters in the shape of a blood red liquor carrying small amounts of gold.

The first charge of coarse concentrates, about 5 feet in depth, was treated for seven days, when the extraction was found to be very unsatisfactory. Upon investigation it was found that while from the top few inches of the charge a high percentage of the gold had been extracted, a little deeper down this was much decreased, until toward the bottom no extraction whatever had taken place. Apparently the reason for this was that the oxygen necessary for the solution of the gold was absorbed by the sulphides, though it is possible that something in the nature of a reprecipitation or weakening of the solution as it percolated downward influenced the result.

Further experiments on this coarse material showed that with a charge 20 inches in depth an extraction of between 85% and 90% could be obtained with a thirty-day treatment consisting of fresh "five-pound" solution every twelve hours. This extraction being considered satisfactory on the grade of the material, the entire dump was treated on the same plan, though in the case of the finer reground stuff a satisfactory extraction could be obtained in twenty days time.

A unique state of affairs occurred occasionally in the treatment of some of the fine material which was very badly oxidized, the extraction taking place in a much shorter time—about fifteen days—and with the solution all the time slightly acid to the litmus or phenolphthalein tests. When these charges were found to be "bad ones," they were carefully watched as to precipitation of the gold, and the number of gold and the number of "doses" of solution lessened to save cyanide. The acidity in these cases was due to salts insoluble in the preliminary water washing, and the rapidity of the solution of the gold due possibly to the action of nascent hydrocyanic acid, but probably to the more free condition of the gold. The gold left in the residues was found to consist for the most part of comparatively coarse inclosed particles as was shown by pulverizing and panning.

Experiments were tried in the direction of using a warm solution, agitation, and sodium peroxide to hasten extraction of the gold. The two first, while somewhat beneficial, were not used because, primarily, the initial cost of installing suitable apparatus was not warranted with the small definite amount of material to be treated. Sodium peroxide was used to a considerable extent, for while it did not accelerate the extraction of the gold very materially, it was found that an increase in the amount of silver extracted more than paid for its use.

Care as to the ordinary rules of cyaniding apply in the case of treating sulphides in the same way as to other ores. The effect of organic matter in precipitating or preventing the solution of gold, for example, is a matter upon which very little stress has been laid, and the use of a mixture of asphalt and coal tar is even recommended in some of the common

hand books on the cyanide process as a substitute for P. & B. paint. The result of using coal tar inside the tanks is of course disastrous, for extraction practically ceases as soon as enough of the organic matter is dissolved by the solution. Two cases of this kind have come under my notice in California, but as both were very small plants and were both destined to close down very shortly for lack of material, the defect was never remedied. In one of the large dry crushing plants in Utah a similar case occurred, but in a different way. As cold weather approached, the superintendent had a large stove placed in about the center of the tank room with a T overhead and long lines of stove pipe extending above the tanks to each side of the building. An oily distillation product from the coal used in the stove soon condensed in sufficient quantities to drip from each joint of the pipe into the tanks. Extraction of gold soon stopped, but as the property went into the hands of a receiver a few days later for other reasons, the cause was never investigated.

To return, however, to the sulphides, the advisability of cyaniding concentrates in the raw state, or to roast and cyanide, to roast and chlorinate, or to ship to the smelter, is a question to be decided by a variety of considerations, such as the amount of material to be treated, distance from smelter, value of material, cost of roasting, etc. Such points as the percentage extraction, time of treatment, consumption of cyanide, etc., can be readily determined by a little preliminary laboratory work and with a fair degree of accuracy. In the high grade pyrites of the Mother Lode district of California the gold may be enclosed in such a way as to require extremely fine grinding for direct cyanide treatment, but the process as outlined above has been successfully used in several sections other than the one mentioned on concentrates as received from the mill.

The great drawback is, of course, the necessity of large tank capacity and floor space to secure a satisfactory daily tonnage, but in those sections where an out-of-door plant is not precluded by climatic conditions this consideration is less serious. The shallow charge is, I have reason to believe, a point which has not received in this country the consideration of which it is worthy in the designing of large plants for difficult direct cyaniding ores.

R. C. HARRISON.

Cromberg, Cal., Jan. 9.

## Methods of Assaying Gold Telluride Ores.

Mining men in certain districts of the United States will be interested in Bulletin No. 253 of the United States Geological Survey, in which the subject of inquiry is the accuracy of the crucible assay method for telluride gold ores. The main point definitely established is the fact that the doubts which have been entertained as to the accuracy of the dry method are not well founded. It is clearly determined that the fire assay by crucible for gold telluride ores gives results which are quite equal to those obtained by the wet method, provided due corrections are made for slag and cupel losses.

The gold loss in the slag is very small, but the cupel losses are very appreciable. The cupellation loss of gold by volatilization is generally slight as compared with that by absorption. At a temperature which allows the formation of abundant feather litharge, the volatilization is negligible, or is perhaps compensated by retention of lead. The case is otherwise, however, at high temperatures, as the volatilization may then average one-half of that by absorption in the case of a quartation alloy. The loss of gold by absorption is very important, and is influenced far more than is generally supposed by slight changes in temperature. It is greater with pure gold and alloys poor in silver than with alloys rich in silver.

The experiments of W. F. Hillebrand and E. T. Allen, the authors of the bulletin, failed absolutely to show the need for a higher temperature at the end of cupellation with gold beads than with those of silver. The most exact results were obtained when feather litharge was still abundant at the time of brightening. Furthermore, it is altogether unnecessary to have gold beads in the muffle for some time after brightening to remove the last of the lead, for there is no loss in weight from so doing, but, if anything, a very slight tendency to increase. The results on absorption, as influenced by the amount of lead used in cupellation, were inconclusive. The error caused by the retention of lead in the beads is serious, if the results of two careful tests are to be depended on, which show 0.30% and 0.37% of lead. The amount of this retention is not lessened by leaving the beads in the muffle for some time after brightening.

Silver can be completely extracted from quartation alloys by nitric acid; but more than two repetitions of the acid treatment and subsequent washing are called for, if any certainty of complete extraction is to be expected.

Tests made with mixtures of pure nitrous and nitric acids show that the solvent action of the nitric

acid is so slight, if indeed there is any at all, that it need not be considered as a possible disturbing factor in parting. It was similarly shown that the losses in parting with pure nitric acid, whether traces of gold really dissolve or not, may be ignored, in an ore assay, at least.

This bulletin, which is entitled "Comparison of a Wet and Crucible-Fire Methods for the Assay of Gold Telluride Ores, With Notes on the Errors Occurring in the Operations of Fire Assay and Parting," is among the Survey's free publications. It may be obtained on application to the Director of the U. S. Geological Survey, Washington, D. C.

## THE PROSPECTOR.

Nothing so stimulates a prospector as a rich strike. When some fortunate searcher finds rock matted with gold, each receives a new supply of energy, and, with renewed confidence in his own ability and luck, strikes out once more in the quest of other bonanzas as yet unknown. The development of the West owes a great debt to the prospector, for without him the discovery of new mineral regions would be of rare occurrence. He is the pioneer who penetrates the mountain fastness and who with his patient burro plods wearily over the cactus-strewn sands of the desert, where the heat radiation of a summer's day gives everything a metallic glare, and no one but a prospector would remain if not compelled to. The winter is the time for the prospector in the desert regions of the Southwest, and in summer he can be found wending his lonesome way amid the peaks and crags of the mountains. The events of the past year have abundantly shown that the old-time prospector, who was declared to be passing away, is only succeeded by a younger generation of his genus, who, with a determination equal to that of his predecessor of former years, but with a broader knowledge of his craft, has taken up the good work, who seeks not less industriously, but more intelligently, for the veins and deposits, the finding of which he believes will mean a fortune to him. Often his efforts are vain, and again he is more fortunate and discovers a mine; but mines are made, and he often sells out before its great value is proven. The old-time prospector was a giant in his day, but he was more apt to be controlled by prejudice than his more modern prototype, who has learned to neglect nothing, to test anything that looks like mineral and to "locate it" should it offer sufficient promise. An instance of this may be noted in western Arizona, where a few miles from Fort Mojave the Moss mine was discovered and worked over forty years ago; but the rich veins of Gold Roads and others of that vicinity were entirely overlooked, though outcropping boldly on the mountain side. The prospector is becoming broader in his knowledge and in his methods, but he has much that is of value to him still to learn.

The mineral specimens from Austin, Oregon, are grano-diorite in greater or less stages of alteration. The country, judging from the description accompanying the rocks and from the specimens themselves, is sheeted—traversed by a great number of parallel fissures, due to pressure. Into this sheeted zone waters have penetrated and affected the normal rock by removing some constituents and depositing others. Nos. 1, 2 and 4 are evidently from the same magma. No. 1 shows abundant quartz with plagioclase phenocrysts in a feldspathic mass, probably largely orthoclase. Hornblende is present, but not abundant. No. 2 is very similar to No. 1. It shows a little pyrite. No. 4 is also like Nos. 1 and 2, but contains less plagioclase and more pyrite than No. 2, which in places the hornblende is being replaced by pyrite, an interesting occurrence, and one which often accounts for the appearance of gold in granitic rocks. No. 3 is somewhat different from the others and is apparently a dike in the grano-diorite. It is somewhat coarser in texture than the others and is the only one of the lot showing mica (biotite), excepting No. 5, which is otherwise almost identical with No. 1. No. 6 is a small vein of quartz and calcite, with pyrite and probably also gold, formed in a favorable place where there has been an open seam or a crushed layer of the original rock. Albite is a variety of plagioclase—a sodium aluminum silicate. Aplites are a variety of granite occurring in dikes, of uniform grain composed of quartz and feldspar, but no hornblende or mica, or only a little greenish-white mica. The dikes may be of the width of a fraction of an inch or may be 100 feet wide or more. Often altered and silicified, it presents the appearance of quartzite.

The mineral specimens from Ibapah, Utah, are: No. 1. Limonite (iron oxide) pseudomorph after pyrite. That is, these crystals were originally pyrite (iron sulphide) and were changed by oxidation to iron oxide. These are of very common occurrence and of no particular value. Occasionally crystals of this character are gold bearing. In fact, if the original pyrite was auriferous the limonite would be also. No. 2 is volcanic ash. No. 3 is quartz with arsenical iron sulphide (mispickel). The greenish stain is due to slight alteration of the original mineral.

# Methods of Renewing Old Timbering at the Dives-Pelican Mine, Silver Plume, Colo.

Written by J. F. McCLELLAND.

The Dives-Pelican mine is one of the oldest in Clear Creek county, having been in operation almost continuously for more than thirty years. In its early history the high cost of labor, transportation, supplies, etc., made it impossible to mine at a profit any but high-grade deposits of ore. Practically the same policy has been followed up to the present time, with the results that the old stopes contain large quantities of ore of too low grade to ship directly to the smelter. Recently there has been a combination of several properties and it is proposed to make the ore in the old stopes the basis of large-scale mining operations.

Many of the old workings have been abandoned for a long time and have caved in. In most cases the drifts were driven in a soft porphyry, which swells

the walls of the drifts require support. They are rarely strong enough to carry stulls and the stopes are supported in most cases by ordinary three-quarter sets. The standard set, with its dimensions and framing, is shown in Fig. 1. Round timber is used exclusively and is mostly native spruce obtained in the vicinity of Silver Plume. The posts of the sets are usually 10 inches and the caps 12 inches in diameter. No sills are used. The posts are either braced to the track, as shown in Fig. 1, or else the feet are kept apart by a 6-inch timber spiked in place on a level with the ties and extending clear across the drift. The sets are lagged with poles from 4 inches to 6 inches in diameter. The side lagging is placed as shown in Fig. 15, and the space behind the pieces filled with broken rock. The timber in the main sets has an average life of from four to six years, but the lagging does not last as long as this. The pressure of the walls and the overlying ore is made evident by the fact that old drifts which are still open are from 6 inches to 1 foot lower and narrower than they were originally.

Before an old set can be taken out the lagging around it and on each side of it must be replaced. At the same time the drift is restored to its original cross section. The lagging is replaced one stick at a time, beginning with that in the roof. Usually the weakest of the old poles is pulled down first—with a pick or bar. Some broken rock will fall at the same time, but generally there are enough large lumps of ore in the stope above to wedge and hold for a short time. If necessary, the hole made in this way is enlarged with a gad and a new lagging pole is inserted, resting at one end on top of the lagging of the set last replaced, and at the other on short blocks set on the caps of the old set (P, Fig. 15). The adjoining lagging pole is then pulled down and replaced in the same manner, the process being repeated until the whole roof has been relagged. This method of putting in the lagging gives the completed work a peculiar appearance, as the lagging poles are inclined downwards instead of upwards, as is ordinarily the case.

The side lagging is taken out and renewed in a similar way. As a general rule, this work begins at the top and proceeds downward, but the presence of fissures and loose slabs of rock may reverse this order. Much work with a gad is usually necessary to get sufficient room to set the side lagging far enough back so that they will take a new set. The forward ends of these lagging poles are blocked against the old set, as shown in Fig. 3.

When new lagging poles have been put in place all around the drift, a false set (Figs. 2 and 15) is erected about 6 inches behind the old set. This is a three-quarter set, made of 6-inch timber, with its outside dimensions slightly greater than those of the standard set. The posts are sunk in hitches 6 or 8 inches deep and are braced to the track. This set is also braced back to the last new set to prevent its overturning under pressure (Fig. 15). The false set is used over and over again, and, for convenience in erection and removal, a false cap (r, Figs. 2 and 15) is used to brace the heads and posts apart, instead of the notch used in the regular set. If the work is carried out properly the cap of the false set fits snugly against the new top lagging and the posts are driven into place with a sledge. If the top lagging poles are too low they may often be raised by putting a drill column under the cap of the false set and using it as a jackscrew. The drill column is of great service also in placing the timbers of the main sets and for many other purposes.

The side lagging is then wedged firmly against the posts of the false set, and the lagging in front of the old set is replaced in exactly the same manner as described above. The rear ends of the side lagging poles, however, must be caught by the posts of the false set, as shown in Fig. 15, so that these lagging poles are cut longer than would otherwise be necessary.

When this has been completed the old set is knocked out and the new one erected in its proper position. The side lagging is then driven ahead to a firm bearing on the new set, and the false set is removed. The same cycle of operations is repeated to renew the next set.

The details of carrying out this work are varied to meet different conditions, as, for instance, in replacing half sets instead of three-quarter sets. Where the ends of the lagging butt on top of the cap instead of overlapping, two false sets are necessary, one on each side of the old set, but otherwise the operations are the same.

A timberman and his helper will average about one set per day of eight hours. The cost of this work per set replaced is approximately as follows:

Timberman .....	\$2 75
Helper .....	2 50
Timber (including framing) .....	4 00
Tramming, mucking, etc. ....	70
Total .....	\$9 95

Since the sets are 4 feet 8 inches apart, the cost is about \$2.15 per foot of drift retimbered.

Quite a little broken rock and ore will fall into the drift in doing this kind of timbering. This is often a convenience, since it gives the men something to stand on while replacing the back lagging. Its amount varies greatly with the character of the

material encountered, but with careful work under ordinary conditions it should not exceed three tons per set. Part of this broken material is used as a filling behind the side lagging.

(TO BE CONTINUED.)

## Charcoal Burning.

In mining regions charcoal is a very useful material and in some things is absolutely necessary. It is useful in the blacksmith shop and in the assay office, and in some camps is used extensively in smelting operations. The following, from Fuel, gives a good description of the art of burning charcoal and will possibly prove valuable to those who care to burn small pits for their own use or for the market:

The best site for a kiln is one that has been used before—the ground is thoroughly dry and is covered with absorptive charcoal dust. The kiln usually consists of two tiers of wood, one upon the other, placed as straight up as possible, the smaller pieces inside, the thicker pieces in the center and the smaller pieces again toward the outside. When two stories have been piled up in this way, more wood is laid horizontally across the narrow top. This kiln is gradually shaped like a dome. All openings are then carefully filled in, in order to prevent unnecessary drafts, and the whole is made as firm as possible.

A passage is now constructed from the outside of the kiln to the flue in the center, or a log of wood which has been placed previously in position is drawn from under the bottom tier, leaving a hollow kindling passage, in which, when the kiln is completed, a torch may be inserted to set fire to the shavings. An important work is the covering of the kiln. Supports of various kinds are placed in position to save a relapse under the weight of the coverings, of which there is both an inner and an outer. The kiln is first tiled, as it were, with thin sods, overlapping each other. Then the outer covering is applied, consisting of loamy forest soil and charcoal dust, well mixed and firm enough to exclude air and retain the heat, and at the same time soft enough to allow steam to escape, and to yield without cracking, as the kiln gradually sinks during the burning. A windbreak is constructed, if necessary.

Early in the morning, when the air is still, a torch of pine is inserted in the passage before mentioned, and the flames seize hold of the dry twigs and shavings in the flue. At first, when the dome becomes hot, steam and thick smoke arise from the top; if it all is well, the smoke should give way to flame, and a not unpleasant, pungent odor should be noticeable. This is a sign that carbonization is in progress. After a few hours charcoal will form in the dome, which will gradually sink in.

Should the sinking be irregular, it is a sign to the charcoal burner that the kiln is burning unevenly. There is too much draft from one quarter, or too little in another; or some of the wood in the kiln is burning quicker than other pieces. This state of affairs must be remedied by boring draft holes or applying water, as the case may require.

On the second day after kindling the first vent holes are made. These holes, bored through both coverings down to the wood, in two rows to leeward, help to regulate the burning, and also give indication when the carbonizing process nears completion. At first smoke and steam issue through them, and after a while the smoke turns blue, which is a sure and certain sign that the charcoal is burning, and this, of course, is the last thing the charcoal burners desire. The holes must be closed immediately with soil or turf and a fresh row opened lower down the side.

## A Need for Legislation.

TO THE EDITOR:—In preceding numbers of this paper the unfortunate trend of the California law of underground waters, hostile to mining interests, was pointed out. In the desire to protect farmers in the arid southern parts of the State, a rule has been adopted which threatens to put the drainage of mines under heavy restrictions. To the authorities cited can be added another, which has since reached my attention (99 Am. St. Rep. 79, note), wherein the writer thinks legitimate and ordinary mining may be no defense under the recent decisions, if the water that seeps into a mine comes from neighboring agricultural land, as it is so likely to do. The question is still young, and something should be done to prevent the law settling itself in that form.

In the present session of the California Legislature the civil code will in all probability be revised, under the constitutional amendment adopted at the last election. Some provision could be inserted that would cover this, and provide that mining in the ordinary way, and all work naturally incident thereto, done primarily for the purpose of extracting valuable mineral deposits, is lawful, and may be carried on without liability for diminution of water supply caused thereby on other lands.

Such a provision would certainly be timely. It would avoid much doubt and litigation, and protect

FIG. 1.

FIG. 2.

FIG. 3.

FIG. 15.

and shells off on exposure to the air, making it necessary to support the walls as well as the back of the drift. Much preliminary work, in the nature of reopening and retimbering the old workings, has been necessary before actual mining operations could begin, and this work seems unusual and interesting enough to warrant its description.

RETIMBERING OLD DRIFTS.—As mentioned above,

\*Abstract School of Mines Quarterly.

one of the most important industries of the State. To leave the law in doubt would mean lawsuits until it is settled. To settle it the other way would mean more lawsuits still. The extralateral right to veins has been such a fruitful source of litigation that there is now much discussion over the advisability of giving it up. The new law of underground waters has itself features not unlike giving the farmer an extralateral right to underground water, with much of the uncertainty that follows whenever underground rights are recognized and not limited by surface boundaries.

If the civil code is to be revised, the influence of your readers and of mining interests in general might well demand some provision such as suggested above.

SAMUEL C. WIEL.

San Francisco, Cal., Jan. 16.

## The Genesis of the Copper Deposits of Clifton-Morenci, Arizona.\*

NUMBER IV.—CONCLUDED.

Written by WALDEMAR LINDGREN.

THE CORONADO TYPE OF VEINS.—Almost the only representative of the Coronado type of veins is that

hardly conclusive. It seems as if the dike had been intruded during the epoch of faulting, and the solutions depositing the copper certainly followed the intrusion of the dike.

**GOLD-BEARING VEINS.**—Gold, silver and lead are practically absent from the principal deposits, but it is an interesting fact that they begin to appear in many of the outlying veins somewhat distant from the central mass of porphyry. These veins, in which copper is apt to play a less important part, have not as yet attained much importance from an economic standpoint.

**CONDITIONS OF GROUND WATER.**—Permanent water has not thus far been encountered in any of the mines in the whole district with which this report deals. Morenci is situated on the hills from 800 to 1500 feet above the principal streams, Chase creek and Eagle creek, and the deepest workings in no place reach farther than 600 feet below the surface. A little seepage from the surface takes place in case of heavy rains, or from the local water supply, and some drifts and crosscuts underneath the town are somewhat damp, especially in the Manganese Blue and Arizona Central mines. The mines at Metcalf are situated on Shannon mountain from 500 to 1200 feet above Chase creek, and here, too, the workings are dry excepting one place in the Shirley tunnel

other hand, the altered limestones and shales are very compact, non-porous and impervious. Where circulation was facilitated by fissures, as in the Manganese Blue and the Joy mines, the rocks may be partly oxidized to a depth of 400 feet, but this is generally a maximum. There is no well-defined plane expressing the depth of oxidation which, on the contrary, proceeds extremely capriciously, entirely fresh sulphides being frequently found very close to the surface.

**SUMMARY OF GENESIS.**—The intrusions of stocks and dikes of granite-porphyry and quartz-monzonite porphyry, which took place in late Cretaceous, or early Tertiary times, produced an important contact-metamorphism in shales and limestones of Paleozoic age, which happened to adjoin them. This metamorphism resulted in metasomatic development of garnet, epidote, diopside, and other silicates, accompanied by pyrite, magnetite, chalcocite and zinc blende. The sulphides are not later introductions, but contemporaneous with the other contact minerals.

The contact zone received substantial additions of oxides of iron, silica, sulphur, copper and zinc, enough to form good sized deposits of pure magnetite and low-grade deposits of chalcocite and zinc blende, all of which are entirely unknown in the sedimentary series away from the porphyry.

Town of Morenci, Ariz. Smelter on the Right.

Metcalf, Ariz. Arizona Copper Co.'s Works in Center.

of the Coronado lode, which crops on the summit of Coronado ridge about 2000 feet above Metcalf. It presents the unusual feature of a fissure vein following one of the principal faults of the district with a throw ranging from 1000 to 2000 feet, and it is traceable for nearly 2 miles, finally disappearing towards the west under the basaltic foothills of Eagle creek. The fault zone, which is from 50 to 200 feet wide, is followed by a diabase dike which has been crushed and partly deformed. Oxidized ores, malachite, azurite and chrysocolla, of medium to poor grade, occupy irregular shoots in the surface zone, but are replaced at a depth of from 200 to 300 feet by chalcocite ores. At some points the latter, however, reached the surface. Explorations during the last two years are reported to have developed large bodies of these, even at a depth of 500 feet below the surface. The evidence—as far as it goes—here, too, points to secondary origin of chalcocite and its derivation from pyritic ores, but here, as well as at Morenci, the maximum depth attained by the secondary chalcocite has not been fully demonstrated.

The Coronado lode is formed later than the Morenci type of veins and subsequently to the intrusion of diabase, which is younger than the porphyries of Morenci and Metcalf. Regarding the relative age of the diabase and the fault fissure, the evidence is

where a winze struck some standing water. The few shafts and prospects sunk in the bottom of Chase creek are the only places containing permanent water. The Copper King mine, situated a few hundred feet below the summit of the mountain of the same name, has a shaft 600 feet deep, and in it some crevices containing water have been found which soon drained out and no more has since come in.

The present stand of the water level, except along the creeks, is practically unknown. It probably rises as a slightly curved surface from the creek levels in towards the high hills. The total amount of water stored below this water level is probably small.

**DEPTH OF OXIDIZED ZONE.**—The presence of products of direct or indirect oxidation shows the depth to which oxidizing waters or the sulphate solutions have penetrated; but the porphyry and the metamorphosed limestones should be separated, because they act very differently. In that part of Copper mountain which has been explored, the average depth of the lower limit of the chalcocite zone is 400 feet, but it increases in places to 500 or even 600 feet. To this depth from the surface the sulphate solutions descended, and along important fissures they may have gone somewhat further. But the solutions not only followed fissures, but penetrated the porous, sericitized porphyry with considerable ease. On the

In view of the evidence, I consider it impossible that circulating atmospheric waters have effected these changes. The occurrences of metamorphosed rocks are manifold and found under many varying conditions; there is only one common factor and that is the presence of the porphyry. It is shown that the porphyry-magma contained much water which held dissolved various salts, among them some of the heavy metals. Sodium chloride and ferric oxide probably predominated. I believe that it contained all of the substances mentioned above, and that large quantities of this gaseous solution (for the critical temperature must have been exceeded) dissolved in the magma were suddenly released by diminution of pressure as the magma reached higher levels and forced through the adjoining sedimentary beds, the purest and most granular limestones suffering the most far-reaching alteration and receiving the greatest additions of substance. It is thus held that a direct transfer of material from cooling magma to adjacent sediments took place. The formation of garnet indicates large gains of ferric oxide and silica. If the magmatic waters carried iron only as ferric oxide some of it must have been reduced to magnetite during the metamorphism, for the latter mineral is much more common than the specularite. These contact-metamorphic deposits often occur at the immediate contact of the main porphyry stock and the

\*Abstract Trans. Am. Inst. Min. Engs.

limestones. But more commonly they seem to be connected with dikes of the same porphyry close to the principal mass, these dikes being probably more highly charged with magmatic waters.

It is shown that fissures and extensive shattering developed both in porphyry and altered sediments after the congealing of the magma, and that these fissures and seams were cemented by quartz, pyrite, chalcocite and zinc blende, forming normal veins largely of the type of replacement veins. The amount of copper contained in these is usually small, though in places possibly large enough to form pay ore. The bulk of the veins consists of pyrite. Two classes of veins may be distinguished. The usual type is practically always connected with granite-porphry or quartz-monzonite porphyry recurring in this rock or along dikes of the same. The smaller division consists of those connected in their occurrence with diabase dikes. The genesis of the former type will first be discussed.

As far as the metallic minerals are concerned there is a striking similarity between the veins connected with porphyry and the contact-metamorphic deposits, the only difference being in the magnetite, which does not occur in the veins proper and only subordinately in certain of the altered wall rocks. A relationship is also clearly seen in the remarkable action of the vein solutions on the adjoining wall rock wherever this is limestone, tremolite and diopside being formed in it by replacement. On the whole, iron and silica are the main substances added, during con-

the eruption of the Tertiary basalts and rhyolites. Oxidation thus acted on them for a very long period.

The irregular and tabular deposits in limestone and shale have obtained their present form, partly by direct oxidation and partly by the influence of sulphate solutions derived from the disseminated chalcocite due to contact-metamorphism; a great enrichment has taken place, due to decrease of volume and addition of copper from the circulating sulphate solutions. Some of the oxidized deposits in shale, however, may be wholly due to absorption, exerted by the kaolin in the shale on these sulphate solutions.

In practically all of the veins, the surface zone of poor ore is due to the direct oxidation of chalcocite. The solutions from this part descend and add richness to the upper part of the remaining chalcocite zone. But at the present low stand of the water level and the exceedingly dry climate, the lower limit of the chalcocite zone is probably almost stationary.

The copper deposits of Clifton and Morenci are thus believed to have been formed primarily by mineral-laden magmatic waters, partly acting as gas and partly as liquids, and in both cases derived from a magma of granite-porphry. These solutions were evidently directly released from the magma without a preliminary concentration in pegmatitic or aplitic dikes, which, indeed, do not occur in this district in association with the porphyry. It is perhaps superfluous to emphasize that these conclusions are not generalizations, and that this mode of origin is not necessarily that of all other metalliferous veins.

Detroit Copper Co.'s Concentrator, Morenci, Ariz.

tact-metamorphism, as well as during the vein formation.

As to the depth at which the deposition took place, no possible evidence is available on account of lack of data concerning the extent of erosion. But from stratigraphic consideration, it is not likely that the depth from surface was more than 2000 or 3000 feet. The cause of the deposition was no doubt a decrease in temperature, just as the deposits are formed in the cooled fluid inclusions. I think it likely that, in most cases, the solutions were present as liquids, for, assuming that the waters communicated with the surface, neither pressure nor temperature could have been high enough to reach the critical point.

The veins connected with diabase dikes are few in number, and the opportunity for their study has been limited. It seems risky, therefore, to express a definite opinion on their genesis, except that the copper and iron sulphide in all probability were derived from the diabase itself, either by means of magmatic or heated atmospheric waters.

The deposits thus far described are, in general, of low grade, only rarely containing enough copper to be classed as economically important. Those in shale or limestone consist of disseminated sulphides, in places irregularly concentrated, or accumulated along certain strata, according to the well-defined tendency of contact-metamorphism. Those in porphyry consisted of heavy veins of pyrite and a small amount of other sulphides, surrounded by zones of dissemination of the same sulphides.

It remained for the surface waters, as erosion gradually exposed the deposits, to alter and enrich them in manifold forms.

From the evidence presented above, it must be concluded that some of the deposits, especially the fissure veins, were laid bare by erosion, and attacked by surface waters at an early date, probably before the principal faulting movement, and certainly before

The earlier processes of magmatic origin produced low-grade deposits of pyritic ores, and the final concentration to payable ore bodies has chiefly been effected by descending and oxidizing surface waters of atmospheric origin.

### Electroplated Copper Plates in the Battery.\*

Written by F. W. CINDELL.

The system of using silver-coated plates as an aid to extraction of gold by amalgamation was introduced on the Homestake G. M. Co. of Lead, S. D., by T. J. Grier, general manager of the company. As stated in a recent paper by C. W. Merrill on "The Metallurgy of the Homestake Ore," the Homestake ore is a "hornblende, garnetiferous schist or slate, which has been crushed and infiltrated with free silica and pyrites, the latter being about 5% or 8% of the ore, and comprising pyrite, pyrrhotite and traces only of chalcocite and arsenopyrite." The company has 1000 900-pound stamps, dropping 10½ inches eighty-eight times a minute with a 10-inch discharge, and crushing about four tons of rock per stamp per twenty-four hours. A No. 8 steel needle (.022 inch diameter) slot screen is used, equivalent to about a 1024 mesh-woven wire screen. On one side of the chuck block is fastened a copper plate, which is the only amalgamating plate in the mortar, and is dressed once in twenty-four hours. Mercury is fed into the mortar boxes. Each outside plate is 4½ feet by 12 feet, there being four rows throughout the mill—that is, there is one copper plate and three electro-silver-plated copper plates for each battery.

The life of the electro-plating on a copper plate

depends on the thickness of the plating, the tonnage crushed, fineness and character of ore, the quantity of water and velocity of flow, inclination of plate, the care the plate receives at the hands of the dresser, and the kind of tools used, while perhaps other influences are exerted which affect its longevity. These plates are also dressed once in twenty-four hours, care being taken to remove the least possible quantity of the plating. Two ounces of silver per square foot is the thickness of the plating, and under ordinary conditions their life may be placed at two years. The position of these plates makes little difference, for in some cases they are not in the mill at all, and do just as well, perhaps better, as they are then not subjected to that terrific vibration which we all know is anything but an aid to amalgamation. In a 200-stamp mill there are 160 plates with an amalgamated surface of 8640 square feet.

In the mills of the Rand with, perhaps, one exception, it is the practice to have but one row of plates, 5 feet by 12 feet, with an area of 2400 square feet in a battery of 200 stamps. Now, compare this figure with the former case, and you get a difference of 6200 square feet. In answer to this it may be said that on the Rand 95% or even 100% of the free or amalgamable gold is recovered on the single plate, and why incur the necessity of increased plate area with extra cost of installment, labor and maintenance.

The percentage of extraction I will deal with later on, but first let me say a word or two in regard to the practicability of the system. No doubt some millmen will scout the idea, and, in fact, in the February Journal of this Society I. Roskelley says: "I do not see that anything would be gained by putting another plate outside the mill." I do not agree with Mr. Roskelley, and will try to prove that he is wrong. The adherence of mercury to gold is a physical mixture of metals, pure and simple. Say it takes the pulp four seconds to pass from one end of the plate to the other; now, if this same pulp is subjected to the same process for a period of sixteen seconds instead of four, is not there a chance of its giving up still more of its values? Theoretically it should, and practically it has been proven. For example, at the Ferreira mine there is a second shaking plate, and P. Carter's contribution in the May Journal proves its value. I do not say that additional plates will catch much free gold, but I do contend they will hold that part of the pyrites, which is barely amalgamable, and has not been caught on the first plate. The additional area of 162 square feet of plate surface to the battery greatly increases the chance of catching what is thought to be non-amalgamable gold.

Mr. Carter also says that two-thirds of the amalgam caught on his second row of plates is from "black sand." The results obtained by him seem to me to be ample proof of the value of these plates, and since Mr. Carter has made a step in the right direction, I should like to see him go still further. I am sure we would watch with interest the results.

The mere suggestion of a third plate would, I presume, receive from most millmen even less approval than does a second plate. The following figures, however, show what has been done by this system. In June, 1902, the Homestake Co. saved on the silver plates alone \$51,333 worth of gold, exclusive of the amalgam and gold-bearing mercury obtained from the launders at the foot of the plates; and in 1903 \$51,672 worth of the precious metal was recovered.

Of the total amount of amalgam obtained—

	Per Cent.
Caught in the mortar box.....	35
Caught on the first row of plates.....	39
Caught on the second row of plates.....	13
Caught on the third row of plates.....	7
Caught on the fourth row of plates.....	6

The amalgam recovered from the lower plates contains a less percentage of gold than that from the upper plates. There is a great variation in the fineness of the bullion between the mortar and fourth plate—

	Fine.
Mortar box and inside plates.....	820
First row.....	810
Second row.....	556
Third row.....	550
Fourth row.....	495

The composition of the ore in question is, roughly, 6% pyrites, 55% silica, and the balance slate. In the Rand ore, approximately, 97% is silica and 3% pyrites. The gold in both is free, and in the pyrites.

The silica is not a very great factor in regard to extraction, as it gives up its gold freely—the pyrites is where the difficulty lies, and it is to this I wish to draw your attention. It seems to me there is not enough difference in the pyrites of the ores to warrant the non-practicability of additional plates in the treatment of Rand blanket, and if the system works well in one case it ought to give proportional results in the other.

The 10-inch discharge, as used by the Homestake Co., is responsible for the great degree of fineness to which the ore is crushed, 78% of the issuing particles passing a 10,000-mesh screen.

I shall not give here the method of electroplating; cost, time required, current, chemicals and mechanical devices used, as that would make a paper by itself.

The principal features of the working conditions described which I wish to emphasize are—(1) the fine crushing, (2) percentage of extraction, and (3) system of plates.

I hope these few remarks will bring forth from the

\* Abstract Jour. Chem. and Met. Soc., S. A.

millmen of this society due criticism, which may be the means of further experiments in this direction. When it has been proven whether additional plates are advisable or not in the treatment of Rand basket, then the object of this paper will have been realized.

### The Sturtevant Clutch.

The automatic clutch illustrated herewith, while designed primarily for automobiles, will be developed by the manufacturers (the Sturtevant Mill Co., Harrison Square, Boston, Mass.), for other large and small mechanisms.

These clutches allow the prime mover to start without load, and at a predetermined speed the clutches grip and drive other mechanism to which they are connected. They are designed to transmit the largest and also the smallest powers, and by multiplying the number, or size (or both), of the friction discs, they are enabled to hold without slip motors of any class. In some Sturtevant designs the high-speed clutch is held out of engagement whenever the torque or resistance is above a predetermined point. Thus the motor is enabled to run fast on low gears, and develop full motor power on the low-gear train. The friction discs run in oil; and the force used to press them together rarely need exceed fifty pounds to the square inch, which is below common bearing pressures. Some machines carry safely on bearings 600 pounds per square inch. Sturtevant clutches require no adjustments after once setting to engage at the speeds wanted.

These automatic clutches are of advantage to many mechanisms requiring a load to be taken on gradually. Applied to automobiles, centrifugal automatic clutches are placed in the flywheel, and each clutch actuates a set of gears in the gear box. There are three changes of speed. The clutch-enclosing flywheel shell is of common size and the clutches give it necessary weight, therefore add none. The flywheel enclosure forms a bath of lubricating oil.

Each clutch consists of a number of thin cast iron disc plates of large diameter that are forced together to grip by the flywheel-enclosed peripheral weights, which move out by centrifugal force (like the weights of a governor) to press the plates together to cause frictional grip. Each weight is held back by springs, and only when rotations cause centrifugal force to overcome the springs can the weights move out to cause the plates to grip. The plates "let go" as

the clutch weights are forced farther out, and, overcoming the second set of springs, force the second-speed clutch discs to grip, and then the car is driven by the second-speed gear; so, as the flywheel runs faster, the direct driving clutch engages. Silent ratchets permit the lower-speed gears to overrun when the higher speeds are operating, but they then do no work.

The manufacturers say that these clutches are so powerful that they can be depended on for sure grip; that they grip and let go just at the right time; automatically change gears just when road resistance requires it; change gears smoothly, it not being possible in changing to break or damage gear teeth; never permit the motor to be stalled, whatever the difficulties of the road or however carelessly the car is manipulated, for if the motor is slowed from any cause below 300 revolutions, the clutches must let go and the motor runs free and does not race, for it is governed; silently act upon all driving mechanisms, for they engage gradually; give every range of car speed, from the lowest to the highest; the car can be moved as slowly as the hands of a clock by silently moving the foot button to throttle the motor and cause the clutches to slip a little; and that they automatically compel the highest driving efficiency.

The Sturtevant multiple disc clutches are covered by several patents; yet more are applied for.

### Map of the Niwot, Colorado, Quadrangle.

Adjacent to the Boulder quadrangle in Colorado is the Niwot quadrangle, which became interesting to the world when oil began to flow at Boulder. It was accordingly surveyed in 1902 by members of the United States Geological Survey, H. L. Baldwin Jr. and F. Tweedy doing the triangulation and F. Tweedy, P. Chapman and F. McLaughlin the topography. The finished map is now ready for general distribution and may be obtained for 5 cents a copy on application to the director of the United States Geological Survey, Washington, D. C.

Besides the oil wells in the southwestern part of the quadrangle, this area contains extensive coal mines, which are centered near the little town of Erie, in the southeastern part of the quadrangle.

Longmont, the most important town of the quadrangle, is the center of extensive sugar beet and canning industries. The whole quadrangle is covered with fine farms, on which large crops of hay, alfalfa and fruit are raised. The high degree of cultivation seen here is due to an extensive system of irrigation. The water for this purpose is taken from Boulder, Lefthand and St. Vrain creeks.

### Coal in Idaho.

The announcement that coal of a very fair quality has been discovered in Thunder Mountain, says Fuel, serves to revive interest in the development of that newest of Idaho's resources. Discoveries of coal have been reported at various points during the past few years, but those who control the loca-

### Balance Equipment of the Denver, Colo., Mint.

The contract for the balance equipment of the new Denver mint has been awarded to Henry Troemner, 911 Arch street, Philadelphia, Pa., and early shipments will begin next month. This contract calls for twenty balances, ranging in size from the most delicate assay balance to huge bullion and coin scales with 6-foot beams, together with a large number of special scale pans, coin boxes and weights. Many of the balances will be specially designed to meet the requirements of the Denver mint.

One of the latter is a 3-foot aluminum beam balance of 1000 ounces capacity for each pan and a sensibility of .001. It is acid proof. The lighter parts are gold plated, all iron parts enameled with acid proof enamel, the whole enclosed in a mahogany case. This balance is to be used in the acid room of the mint and will cost \$860. The set of weights for it range from 500 ounces down to  $\frac{1}{1000}$  ounce. The entire set is in a mahogany block and costs \$200. Another 3-foot aluminum beam balance, with a capacity of 700 ounces and a sensibility of .001 ounce, entirely encased in mahogany, is to be used by the adjuster for standardizing all scales and weights in the mint.

For the assay department there are four of the regular Troemner No. 7 assay balances and one "04" balance, the latter heavily gold plated and of the highest sensibility. In the bullion department will be three 6-foot aluminum beam balances with a capacity of 10,000 ounces in each pan and a sensibility of .01 ounce. Each of the above will be fitted with hard steel hammered pans. Included in the contract are two 5-foot balances with a capacity of 5000 ounces in each pan, two 3-foot with a capacity of 2500 ounces in each pan, and six 3-foot with a capacity of 1000 ounces in each pan. All of the above will be made with aluminum beams, and all will be adjusted to a sensibility of .01 ounce. For laboratory work in the mint two special analytical balances are being constructed, each with a capacity of 100 grams and a sensibility of .05 milligram. These balances will have aluminum beams, agate knives, agate bearings and plate glass sub-bases, and will be acid proof.

To equip the several balances mentioned above, there will be seventy-three solid brass weights of 500 ounces each, and twenty sets in covered mahogany blocks, ranging from 500 ounces to  $\frac{1}{1000}$  ounce in size. For use in weighing coin there are ordered 150 coin boxes of heavy tinned iron,  $6\frac{1}{2} \times 6\frac{1}{2} \times 3$  inches, made in nests of one dozen each. There are also eight large steel pans for weighing bullion, scrap, etc., and six steel strip pans, equipped with suitable handles, for expeditiously handling large quantities of gold or silver coin strips before they go to the stamps.

For use in the deposit weigh room there are thirty-six specially constructed heavy copper boxes with Yale paracentric keys and locks, and two master keys, which will be held respectively by the chief coiner and his assistant.

The entire contract approximates \$25,000, and is believed to be one of the largest orders for balances ever given to one manufacturer.

Director of the Mint Roberts writes that the entire

PATENTED

The Sturtevant Clutch.

soon as revolutions lessen sufficiently to permit the springs to force back the weights and separate the disc faces. In the Sturtevant 1904 car the springs of the low-speed clutch weights are set to permit the low-speed discs to grip and start the car as soon as the motor has reached a speed of 300 revolutions. The low-speed clutch then seizes and drives its gears. When the motor is allowed to reach 500 revolutions,

tions have, as a rule, been unable to develop the properties to a depth sufficient to demonstrate the value of their holdings from a commercial point of view. The coal found in Thunder Mountain is said to have increased in quality and quantity with depth, having been developed about 50 feet. The Pollard mines, in Lemhi county, have been opened up systematically and are yielding large quantities of coal.

A Large Gold Weighing Machine.

equipment will be shipped in time to have it ready July 1st, when the institution will be opened as a coinage mint. It is expected by Director Roberts that legislation will be enacted during this session of Congress authorizing the Secretary of the Treasury to direct coinage of nickels and pennies at San Francisco and Denver mints as well as at Philadelphia, the only place where they are now coined.

# Mining and Metallurgical Patents.

PATENTS ISSUED JANUARY 10, 1905.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

METHOD OF RECOVERING TOGETHER THE METAL VALUES CONTAINED IN SLAG AND MINE WATERS.—No. 779,252; R. Baggaley, Pittsburg, Pa.

Method of recovering values from water containing copper in solution, which consists in passing such water through successive vessels containing iron and causing it to drop from one vessel to other.

EXCAVATING APPARATUS.—No. 779,043; G. H. Hulett, Cleveland, O.

Combination with track laid longitudinally in cut, steam shovel or other excavator thereon, second track parallel with first track, car carrying hopper and conveyer, and feeder located below hopper and adapted to alternately open and close bottom of hopper and force material discharged therefrom into conveyer, of second conveyer for carrying spoil and depositing it to one side of cut.

DREDGER.—No. 779,782; J. Henderson and H. G. Peake, Oroville, Cal.

In dredger, combination with upper and lower wheels, of series of buckets movable over wheels and having alternate projections and depressions, and supporting roll situated between wheels and having co-operating projections and depressions.

ROASTING FURNACE.—No. 779,717; F. Klepetko, New York.

In furnace having plurality of hearths, rotatable hollow shaft passing through hearths, series of hollow arms radiating from shaft and extending into several hearths, series of chambers distributed throughout shaft and communicating with hollow arms, means for permitting circulation therethrough of current of air, and series of deflecting ribs disposed along inner surfaces of hollow arms.

SHAKER FOR CONCENTRATING TABLES.—No. 779,857; J. Klein, Desloge, Mo.

In shaker for concentrating tables, reciprocating rods 21 and 22 slidingly mounted; crank shaft 23 mounted above and transversely of rods; driving rod 30 operated by crank shaft; sliding head 33 rigidly mounted upon reciprocating rods 22 and 23; arm 43 rigidly mounted in inclined position; toggle joint head 46 adjustably mounted upon arm; links connection toggle joint head to sliding head 33 and to driving rod 30; concentrating table; eyes 52 and 53 rigidly secured to forward ends of reciprocating rods 21 and 22; eyes 54 and 55 rigidly secured to concentrating table, links 57 loosely connecting eyes 52 and 54, link 58 loosely connecting eyes 53 and 55; and expansive coil spring between concentrating table and rigid portion of frame.

BELT CONVEYOR APPARATUS.—No. 779,666; T. Robbins Jr., New York, N. Y.

In conveyor belt support, combination of set of supporting pulleys and supporting bearings therefor, bearings carrying pulleys in common plane transverse to travel of belt in position to support belt, and pulleys for bearing against edge of belt to lat-

erally guide it, guide pulleys being mounted in same transverse plane with supporting pulleys.

EXCAVATING APPARATUS.—No. 779,442; J. T. Richmond and N. H. Beebe, Anthony, Kans.

In excavating apparatus, combination with power mechanism and excavator, of carrier mechanism from which excavator is supported, carrier being adjustable vertically, horizontally and longitudinally.

ROLL CRUSHING MILL.—No. 779,566; T. L. Sturtevant, Quincy, and T. J. Sturtevant, Wellesley, Mass.

In roll crushing machine, combination with pair of crushing rolls and shafts by which rolls are carried, of bearing supports or carriers rear portions of which are recessed, bearing boxes movably mounted in supports or carriers, and nests of coil springs housed in rear recessed portions of supports or carriers and yieldingly holding the boxes in working positions, bearing supports or carriers being provided with tie caps hooked over ribbed portions.

SHOVEL.—No. 779,546; W. S. Judd, Cleveland, Ohio.

In shovel, in combination, blade, and tubular socket having on its lower end two integral wings whose upper ends extend laterally on opposite sides of socket piece and are integrally connected together at sides of socket, blade being inserted between wings with upper edge in contact with part which unites them, and being secured to wings.

## Notes on Crushing of Metalliferous Ores in the Stamp Battery in Africa.

NUMBER V.—CONCLUDED.

Written for the MINING AND SCIENTIFIC PRESS by  
F. C. ROBERTS.

In an ordinary battery of, say, 200 stamps, the superficial plate area amounts to 2400 square feet. For the purpose of saving time alone it appears to the writer that it would be a great advantage if this or any area was segregated into, say, three lines of copper plate, each having a superficial area of 800 square feet or more, providing, of course, that the effective conditions of amalgamation were observed.

It would be quite simple, when plate scraping or dressing became necessary, to deflect the pulp from any one line of plates to any other line or lines while this operation was being carried out, and it would then be possible to dress more frequently without having to regard the loss of time.

The number of amalgamators per unit might also be with advantage reduced. It might be urged that the effective principles of amalgamation could not be observed with the plates so far removed from the mortar boxes, as would be necessary in the suggested arrangement, but it is contended that any conditions may be obtained by a simple modification of the plate arrangement. In case of a classification of the product a more elaborate arrangement of plates would become necessary, as the grade of plate, the quantity of water and other factors would require to be made to suit the individual products.

The segregated costs of milling 38,054 tons of ore in a typical Rhodesian mine (capacity of plant 3200 tons per month) are as follows:

	Total.	Cost Per Ton.	Total Cost, %.
Salaries.....	\$ 2,232 14	\$0.060	4.8
White wages.....	4,630 44	0.126	10.3
Native wages.....	1,680 36	0.044	3.5
Native food.....	618 46	0.016	1.3
Stores.....	4,455 28	0.117	9.4
Explosives.....	3 66	0.001	0.0
Fuel.....	5,603 18	0.147	11.8
Maintenance.....	4,141 76	0.108	8.7
Workshops.....	866 72	0.008	0.7
Mill engine and boilers.....	8,553 38	0.224	18.2
Pumping station.....	2,157 40	0.056	4.5
Electric lighting.....	520 02	0.013	1.1
Transport.....	28 40	0.000	0.0
Native hospital.....	54 22	0.001	0.1
Native labor supply.....	30 80	0.000	0.0
Pumping (from mine).....	1,658 46	0.043	3.5
Compound.....	827 48	0.014	1.1
Sorting and crushing.....	8,793 44	0.230	18.8
Assaying.....	1,236 58	0.037	2.2
Totals.....	\$47,552 08	\$1.245	

It will be observed that the account, "sorting and crushing," has been charged to milling in the above statement, whereas if this account be excluded the total milling charge amounts to \$38,769.14, or \$1.015 per ton milled. This account was included as being relevant in this case and it is sometimes the custom to charge it direct to milling, although the writer prefers to treat "sorting and crushing" as a separate account.

In Rhodesian practice the cost of stores in a mill shows some little fluctuation, according to the distance to be covered by wagon transport. A very fair idea, however, may be obtained from the following figures which have been compiled from the average cost per unit of the several articles at four different milling properties, taken over extended periods.

The tabulation below refers to 28,751 tons crushed:

	Total.	Cost Per Ton.
Mercury.....	\$ 46 02	\$0.0016
Waste.....	28 64	0.0010
Oils and lubricants.....	463 76	0.0161
Shoes.....	1,585 50	0.0554
Dies.....	776 34	0.0270
Cam shafts.....	91 26	0.0031
Stems.....	51 60	0.0017

\*Mill closed down.  
†Mill under construction.

The monthly output of gold in (bullion) ounces from Southern Rhodesia varies from 18,000 to 24,000 ounces (the value of the ounce ranging between \$12.40 to \$18.60), according to the fineness. The large fluctuation in the output is due to periodic stoppages, which become necessary in order to allow the development work to be extended.

CORRECTION.—In the issue of January 14, on page 21, third column, line 14 from the top, the statement that 21 pounds of lime per ton of ore was used to neutralize acidity should have read 2 pounds.

## MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

### ALASKA.

The fluctuations of the production of precious metals in Alaska during the last five years are noted in a recent bulletin of the U. S. G. S. From 1898 to 1900 there was an increase in value of over \$5,500,000, followed by a falling off in the succeeding year of nearly \$1,500,000, which was more than regained in 1902. The output of 1903 shows an increase of \$300,000. The production of quartz mines during this period has not varied from year to year over 20%, and the value of their silver output is so small that it can be disregarded. The fluctuation of the total production is a reflection of the status of the placer mining industry. Moreover, as nearly five-sixths of the gold derived from placers comes from the Seward Peninsula, it is patent that the production of this district is the governing factor in the entire output. The rapid exploitation of the rich placers at Nome, in 1899 and 1900, especially the easily mined auriferous beach gravels, brought up the total values with a bound, but this was followed by a reaction; for two favorable seasons sufficed to almost exhaust the beach placers, and to make serious inroads on some of the bonanzas of the shallower creek deposits. This fact, combined with a rich harvest of legal complications which had arisen at Nome, together with a very short and unfavorable season, led to a discouraging falling off of the placers in 1901. Meanwhile, however, the more enterprising operators had recognized the necessity of improving the mining methods, and consequently the building of ditches and the introduction of hydraulic methods had by 1902 gone far enough to bring the production up over the \$8,000,000 mark again. The same general conditions existed through 1903. Though many extensive plants are being installed and 100 miles or more of ditches are being constructed in the peninsula, but few of these are in operation. The development of the bedrock mines is relatively slow, and much the larger part of the lode gold comes from the famous Treadwell group. In the Juneau district much activity was displayed in lode mining during 1903, and some large properties changed hands. A few small gold mines were in operation in the Ketchikan district and other properties were prospected, but it was on the copper deposits of this region, rather than on the auriferous veins, that the attention of the mining public was centered. Gold-bearing quartz veins have been found in other parts of Alaska, but few of these have been developed so far as to reach a productive stage. Perhaps the most significant feature of lode mining in 1903 was the establishment as a commercial success of the Big Hurrah quartz mine on the Seward Peninsula. This little property, with its ten stamps, represents the only effort at quartz mining in northern Alaska. The production of the Seward Peninsula placers is estimated to be about \$5,000,000, of which probably three-fifths are taken from the Nome district and one-fifth from Ophir creek. The Yukon region, including Forty Mile, Birch Creek, Rampart, Koyukuk, and the Fairbanks district, had an output for its placers of probably \$1,000,000. Most of the camps of this region are so isolated as to make the cost of mining a very large percentage of the production. In only a few instances have extensive mining plants been installed in this field, and most of the gold is taken out in small quantities by more or less primitive methods. The Fairbanks district comprises a dozen creeks tributary to the Lower Tanana, from which they are only 15 to 20 miles distant. The auriferous gravels appear to occur in considerable thickness, and the values though not high are fairly uniformly distributed.

### ARIZONA.

#### Mohave County.

At the San Francisco mine of the Yucca Cyanide M. & Co. at Cedar the shaft will be sunk to the 800 level under charge of C. D. Pickering.—The property of the New Comstock M. Co. has been sold to W. C. Howard and others of San Francisco, Cal., who will equip it with machinery and sink the shaft to a depth of 300 feet.

#### Yavapai County.

The Supreme Court of the United States has decided the case of the United States vs. the United Verde M. Co. of Arizona, which was a proceeding to recover \$38,000 on account of timber cut from the public lands and used in roasting ore, in favor of the United Verde Co. The regulation of the Interior Department directed that timber should not be used for smelting purposes,

whereas the law authorized miners to cut public timber for "domestic purposes." The opinion was by Justice McKenna, who held that the words "domestic purposes" included the roasting of ore, and a mining company was entitled to cut timber on public land for that purpose. He also held that the Secretary had no authority to promulgate a regulation extending the scope of the law, as will be the effect in this case if ore roasting is to be construed as ore smelting. The opinion affirmed the decision of the Arizona Supreme Court. Justices Harlan, Brown and Peckham united in a dissenting opinion, based on the theory that ore roasting is not a "domestic process."

### CALIFORNIA.

#### Amador County.

The Treadwell mine, near Volcano, will be started by S. Drake of Seattle, Washington, under superintendence of B. K. Worley.

#### Calaveras County.

At the Reed mine a hoist and mill are being put up. The mine work is under Foreman George Glover.—J. S. White of Oakland has begun operations on his gravel property at the Joses place on the Calaveritas road. M. H. Sunderland of San Andreas has charge.—The Johnson property, on the San Andreas channel, is being worked by D. Fricot, under charge of J. B. Luddy.—Ore has been found at the Blue Jay mine, on the Calaveras river, near Mokelumne Hill, the tunnel having been run 1084 feet, at the end of which a 30-foot crosscut was run. C. H. Blake is superintendent. W. H. Clary, superintendent of the Clary G. M. Co., near Murphys, will build a stamp mill.

#### El Dorado County.

S. Collins and W. Bacchi will develop their quartz mine, near the Esperanza mine, near Garden Valley.—W. Russell and J. Wakefield are preparing to hydraulic their mine in Happy flat, near Garden Valley.

#### Kern County.

The Corona M. Co. of Randsburg will put in new mining machinery.

#### Mariposa County.

(Special Correspondence).—It is stated on good authority that the Green Mountain copper mines at Lewis, 10 miles northwest of Raymond, are to be developed. Several men are cleaning out one of the old shafts, preparatory to further development, and materials are being hauled to the mine, including lumber, powder and general supplies. This is one of the most promising properties on the copper belt in this county and much is expected of it. The copper occurs in a large zone in mica schists, being chiefly in a state of semi-oxidation. The ore in the mines on this belt from Daulton to White Rock are oxidizing so rapidly that they frequently take fire, not only in the cars, but also in the ore bodies. O. R. Sydney has been owner and manager. Raymond, Jan. 18.

#### Nevada County.

The Buckeye M. Co., T. B. Gray of Nevada City superintendent, will build a 10-stamp mill on its property in Willow valley. The tunnel will be driven until it intersects the shaft, which is to be sunk deeper.

Superintendent F. Zeilert will add ten stamps to the 10-stamp mill of the Zeilert mine in Bear valley; sixteen men are at work.

C. A. Brockington, superintendent of the Orleans mine at Nevada City, will put in an air compressor.

#### San Diego County.

S. L. Ward and L. E. Cooley of Imperial and W. Allen have discovered and located twenty-five claims on an onyx deposit 40 miles west of Mammoth Tank, near San Felipe creek, 15 miles southeast of Borega Springs.

#### Shasta County.

The Southern Pacific spur track from Kennett to the smelter site of the Mammoth C. M. Co. will be 2400 feet long, with 1400 feet of siding at the smelter terminus. It will take two months to build it, as a high trestle, a 40-foot fill and a 25-foot cut are called for. The spur will connect with the main line at the mouth of Backbone creek, on the lower edge of the Kennett townsite. It is to be of standard gauge. Teams and men are at work grading for the smelter and laying foundations for the machinery. Office buildings, bunk houses, stables and a boarding house have been put up.

The Mountain C. Co. has transferred forty men from its smelter at Keswick to the refinery and reduction works at Bull's Head point in Contra Costa and to its acid works at Fleming's point in Alameda county. Six McDougal roasting furnaces have also been shipped and the boarding house at Keswick closed.

#### Siskiyou County.

The Medina G. M. Co., operating the Johnson mine at Oro Fino, are putting in an air compressor and drills, to be operated by water power from the Johnson ditch, and will run a 1500-foot tunnel to tap the Johnson ledge.—J. M. Morrison, superintendent of the Morrison-Carlock M. Co. of Quartz valley, will buy machinery to sink 300 feet from their lower level.

#### Tulare County.

At Whiteriver the Bright Star mine will put in a new mill.

### COLORADO.

(Special Correspondence).—From now until spring a number of fatalities may be looked for, on account of snowslides in certain sections of the State. Already a number of deaths have been reported on this account. The recent heavy snows in the mountains have made it exceedingly dangerous to travel, and especially in the San Juan country, where most of the damage is done by the slides. In most cases, slides are known to come down every winter and the people, traveling through those districts, are always in more or less danger of being caught in them. At times the destruction of property is large. Near Telluride, Silverton and Ouray they have been known to do a great deal of damage to mine and mill buildings which are erected too close to their

path.—At least three bills have been introduced into the State Legislature, now in session, making eight hours a day's work. It is understood that the Western Federation of Miners, who called the strike in the Telluride and Cripple Creek districts some eighteen months ago, on account of there being no eight-hour law passed at the last meeting of the Legislature, are now opposing the measures introduced in the general assembly. It is hoped something may be done at this meeting of the Legislature to prevent such conflicts between capital and labor that the State has been compelled to undergo the past two years.—Reports have been circulated that Wall Street speculators will not permit the Moffat railroad to be completed, and that it is about to be taken over by one of the larger roads entering the State. Mr. Moffat, who is at the head of the road, has said that the road will be completed and that he has the money to carry through the enterprise without the aid of outside capitalists. The road is completed to the top of the range. The completion of this road means much to the northern part of the State, as it will open up a vast area of valuable mineral land now undeveloped and, in the main, unexplored. The past year prospectors have been at work in the territory through which this road is supposed to pass and it is understood have been rather successful, having obtained good assays from mineral which they have discovered.

Donner, Jan. 16.

#### Boulder County.

(Special Correspondence).—The Isabel has opened up ore and work will be pushed. The Boulder County mine has put in machinery. The Mt. Vernon will start up February 1st. This property has been closed down since January 1st on account of the cold weather. The railroad now is within 1½ miles of the camp.

Caribou, Jan. 14.

The Cash mine at Gold Hill is being worked by the American Queen G. M. Co., L. R. Johnson, manager.

#### Clear Creek County.

The Pittsburg Con. M., M. & T. Co. is grading for a mill at the mouth of Fall river for the Dover mine. At Freeland the Brighton shaft has been sunk 500 feet. Manager Ellis is extending the fourth level east to connect with the Freeland extension workings to give an outlet for the surface water through the Freeland extension and Freeland tunnels.

#### Custer County.

J. W. Northrop of Chicago has bought 900 acres at Silver Cliff, including the Geyser, Silver Bar and Diamond mines, and is building an 80-ton mill to test reduction of the different ores preparatory to putting up a 300-ton mill at the Silver Bar mine.

#### Gilpin County.

R. Hastie, Jr., manager of the Otto Schatz M., L. & D. Co., operating the Caledonia property in Lake gulch, is shipping ore to the Golden smelter, through the sampler at Black Hawk.—The Old Town M. Co. of Russell Gulch is putting in a new electric pump with five plungers.—A. Williams of Perigo, foreman of the Gold Dirt mine, says the company intends to build a mill to treat the ores from the Gold Dirt. Three 100 H. P. boilers will be put in.—The Imperial G. M. & M. Co., operating the Mackey and Sarah Jane groups in the Pine district and owning the Mountz & Palmer mill at the mouth of Elk and Pine creeks, is employing twenty men under the management of L. J. Mountz. The milling ores are being saved for treatment at their own mill.—The Golden Sun M. & M. Co., operating between Rollinsville and Boulder Park, is driving its main tunnel from the south side of South Boulder creek into the mountain, under charge of L. A. Shearer.—The Sunset G. M. & M. Co. are sinking to the 825-foot level of the Justice, near Russell Gulch, and are drifting on the 220, 420 and 570-foot levels. J. F. Stanish is superintendent.

#### San Juan County.

Work has commenced on the Hercules Con. mines on Sultan mountain, and T. Kane of Silverton, the manager, states that forty men will be put on the property to continue the Empire tunnel 1000 feet beyond its present point of 2545 feet.—A survey has been made for a tram line from the Mogul mine 1½ mile to the mouth of Dry gulch, below Gladstone.—The Old Hundred tram line is being pushed and will be completed by Feb. 1.

J. C. O'Neill has from the Malchus Bros. of Silverton an option on the Mayflower group on Round and King Solomon mountains, and will continue the Arastra gulch tunnel, now in 300 feet, to cut the Mayflower vein.

W. Fiegel of Silverton is building a Bleichert tramway from the upper workings of the Barstow mine on Red mountain to the mill.

#### Summit County.

The Michigan mine at Kokomo, under charge of G. I. McDonald, is shipping fifty tons of pyritic ore daily.—The Willey mill at Kokomo has been remodeled and new stamps and machinery put in place.—The Union Con. group at Gold Hill is being developed under the management of M. Gagan.

#### Teller County.

(Special Correspondence).—H. D. Williams of Denver has a bond and lease on the Lawrence Gold Dollar, adjoining the Strattons Independence. The shaft is down 180 feet and tunnel 190 feet in length. An electric plant will be installed to drive the tunnel.

Victor, Jan. 14.

(Special Correspondence).—The District Gold Extraction Co., F. J. Buck, manager, is handling fifty tons of ore through their cyanide plant and claim to be making 87% extraction. They are using zinc powder instead of zinc shavings. The ore is taken from a dyke about 20 feet wide and from the surface by a plow and scraper.—The Cripple Creek Homestead Co., on Ironclad Hill, expect to have their new mill in operation about March 1st. The machinery has been shipped. The old mill of the company is kept busy. The new mill will have a capacity of 750 tons per day.

Cripple Creek, Jan. 17.

(Special Correspondence).—Much work is being done on the fifth, eighth, ninth and tenth levels in the Vin-

dicatur mine on Bull Hill. They will start a winze from the 500-foot to the 800-foot levels. The main shaft is down 1200 feet, but no work is being done below the tenth level on account of water. Work will probably not be resumed below the tenth level until pumping arrangements can be made with some of the adjoining mines, especially the Golden Cycle, with which they are in litigation over the pumping proposition. It is claimed that the deep drainage tunnel will not benefit this portion of Bull Hill in the least. Water is being pumped from the tenth to the eighth levels and from there to the surface. E. J. Trevorron is superintendent, and F. J. Campbell of Denver, general manager.

Independence, Jan. 14.

At the Rubie, belonging to the Merger G. M. Co. on Bull hill, ore has been found at 1300 feet by Manager W. J. Storke. Being found at such a great depth, the find disproves the statement of the governmental experts, who are inclined to believe that the ore zone below the 1000-foot point will not result in much good. Operations have been resumed on block 11 of the Work Co.'s property after a temporary close down, during which a new plant of machinery, including an air compressor, was put in. The main shaft of the Moon-Anchor, on Gold hill, is to be deepened. The water level has receded sufficiently to permit of sinking without pumping.

### IDAHO.

Advance sheets of the annual report of State Mine Inspector R. N. Bell show the value of Idaho metal production by counties during 1904: Ada—Gold, \$995,677; silver, \$22,400; total, \$1,019,077. Bannock—Gold, \$2810; silver, \$1110.20; copper, \$2600; total, \$6520.20. Bingham—Gold, \$4360; silver, \$7,040; total, \$4367.04. Blaine—Gold, \$10,424.08; silver, \$527.73; lead, \$354,885.89; total, \$792,590.70. Boise—Gold, \$326,733.99; silver, \$7317.40; total, \$334,050.39. Canyon—Gold, \$8487.51; silver, \$76.35; total, \$8563.86. Cassia—Gold, \$5585.65; silver, \$34.85; total, \$5620.50. Custer—Gold, \$85,452.07; silver, \$284,021.45; copper, \$313,239.29; lead, \$16,881.97; total, \$699,595.38. Elmore—Gold, \$561.60; silver, \$2239.73; total, \$84,934.61. Fremont—Gold, \$561.60; silver, \$3.61; total, \$565.21. Idaho—Gold, \$253,837.10; silver, \$2843.55; total, \$256,680.65. Kootenai—Gold, \$8268.41; silver, \$91,644.18; lead, \$62,092; total, \$162,004.59. Latah—Gold, \$253,960.09; silver, \$1915; total, \$255,875.09. Lemhi—Gold, \$253,960.09; silver, \$59,005.89; lead, \$84,366; total, \$397,331.88. Lincoln—Gold, \$1558.87; silver, \$17.16; total, \$1575.67. Oneida—Gold, \$5394.87; silver, \$16.77; total, \$5411.64. Owyhee—Gold, \$512,512.65; silver, \$1,077,262.23; total, \$1,589,774.88. Shoshone—Gold, \$147,092.94; silver, \$8,380,982.94; lead, \$9,311,200.43; copper, \$364,000; total, \$18,203,275.63. Washington—Gold, \$28,799.30; silver, \$124,288.57; copper, \$25,021.62; total, \$178,109.49. Grand total, \$22,838,299.35.

#### Blaine County.

The Wood River Zinc Co., of Portland, Oregon, will build a 200-ton mill to treat the zinc ores near Hailey. W. E. Prudhomme is president, J. J. Chambréau is secretary and auditor. W. E. Sullivan of Hailey is resident agent in Idaho. J. Williams is general manager. The offices are at 250 Alder street, Portland, and Hailey, Idaho.

#### Boise County.

D. Kennedy of the Lincoln mine at Pearl will put in a 150-ton cyanide plant. A 10-ton plant was built at the mine to test the process and showed a saving of 92%. The new shaft is 85 feet deep.—It is reported that Manager Combs of the Osborne mine at Pearl will build a mill.

#### Idaho County.

At the Lily May, on Red river, 5 miles south of Elk City, owned by the Elk City G. M. & M. Co., J. A. Coverly, superintendent, the tunnel is in 210 feet.

#### Shoshone County.

(Special Correspondence).—The Highland Chief mine, on Pine creek, west of Wardner, has shipped a car of ore averaging 44% lead and 35 ounces silver to the ton.—The Black Horse group, east of the Bear Top mine, near Murray, struck 12 inches of carbonate ore 70 feet from the surface.—The Knickerbocker, in Rosebud gulch, Evolution mining district, below Osborn, has been bonded to T. N. Barnard and E. J. Hunter of Wallace for \$15,000. Work will begin at once.

Wallace, Jan. 16.

M. Glendenning of Wallace reports the Cœur d'Alene output for 1904 as follows:

	Lead.	Silver.	Total
Pounds.	Ounces.	Value.	
Federal.....	94,300,000	3,032,000	\$ 5,366,370 00
Bunker Hill & Sullivan.....	61,438,098	1,094,100	2,991,661 83
Morning.....	29,884,076	507,853	1,441,282 76
Hercules.....	14,000,000	900,000	1,054,250 00
Hecia.....	15,000,876	448,589	836,328 79
Frisco.....	1,400,483	48,845	84,249 60
California.....	977,880	21,918	10,196 43
Silver King.....	230,960	9,520	14,665 58
Stewart.....	195,000	5,250	10,518 12
Gold Hunter.....	184,400	7,200	9,286 40
Monarch.....	118,400	1,120	5,199 60
Terrible Edith.....	87,000	375	1,639 18
Bear Top.....	37,000	375	1,639 18
Blake Bros.....	20,000	800	1,228 00
Safford Bros.....	30,000	750	1,584 37
Snowstorm.....	.....	168,000	96,280 00
Totals.....	217,909,071	6,247,795	\$11,966,374 83

Copper production, \$300,000; gold, \$109,400; grand total, \$12,365,374 82.

These figures differ somewhat from R. N. Bell's estimate.

### MISSOURI.

#### Jasper County.

The Underwriters' Land Co. is putting up an 800-ton plant for concentrating lead and zinc ores from the two incline shafts being sunk at the Yellow Dog, in the Joplin district. It is to be operated by electricity furnished by the Spring River Power Co. There will be three Ingersoll-Sergeant air compressors, each driven by a 20 H. P. Westinghouse induction motor. The mill is to be built in two sections.

### MONTANA.

#### Beaverhead County.

The Polaris mine at Polaris has changed hands and is

to be worked by the first of March. The company is going to put in a smelter. M. Hays has charge.—At Farlin, the Amalgamated Copper Co. is putting in new machinery preparatory to starting operations in the Indian Queen mine, including a 60 H. P. engine, a boiler and an air compressor.

#### Jefferson County.

J. C. Cory of Helena is working the Minah mine, near Wickes.

### NEVADA.

#### Esmeralda County.

R. G. Butler of Las Vegas, Nev., is considering building a road for a freighters' line from Las Vegas to Ash Meadows, 77 miles, with four watering places; Ash Meadows to Gold Center, 85 miles, with one watering place; Gold Center to Breyfogle mines, 9 miles; Gold Center to Goldfields, 70 miles, with four watering places; Las Vegas to Bullfrog, 124 miles; Las Vegas to Goldfields, 193 miles.

J. H. Spiking is building a stamp mill at Goldfield and has ordered a cyanide plant. Water for milling purposes has been developed by wells near the mill.—The Goldfield-Sierra M. Co. has commenced a shaft on the Ajax vein at Goldfield. W. W. Kirby is in charge.—The Goldfield-Sovereign M. Co., in which W. M. Downing of Denver, Colo., is interested, has purchased the Johnson No. 1 and Johnson No. 2 on Banner mountain, the Now York Nos. 1 and 2, 1 mile east of the Johnsons; the Tom Henry, ending the Great Bend on the west, and the Snowflake, ½ of a mile north of Kendall, for \$27,000. F. E. Horton is resident manager. Work has been commenced on Johnson No. 2.—On the Montana-Bullfrog at Bullfrog, M. Walsh has been appointed superintendent. A tunnel will be started to tap the ledge at a depth of 150 feet. The telephone line which H. H. Clark is building is completed to Thorp's mill and will probably be finished to Amargosa by February 15. The new wagon road is practically completed to Amargosa and the distance is shortened to 55 miles.

The Joshua Man G. M. Co. is developing a shaft on the Overlook claim, now 45 feet deep, and a tunnel on the Joshua Man, in 210 feet. F. J. Campbell of Denver, Colo., is general manager and F. E. Brown has charge at Goldfield.—J. McKane has bought the Davenport group, 5 miles east of Goldfield, and will put in a hoist and sink to a depth of 500 feet before cross-cutting.

#### Humboldt County.

The 40-ton cyaniding and concentrating mill at the Golden Eagle mine, near Golconda, owned by the Glasgow & Western Exploration Co., has been started.

#### Lincoln County.

It is reported that C. O. Whiteman of Salt Lake City, Utah, will equip the Panaca mine with machinery.

Superintendent F. J. Harrington is putting in a 60 H. P. hoist for the Quartette mine, near Searchlight, and a 64 H. P. engine for the mill. Settling tanks have been ordered for the mill. The shaft is within 60 feet of the 800-foot level.

#### Nye County.

The Tononah Railroad is widening its tracks that it may be ready to bring broad gauge cars to Tonopah as soon as the Carson & Colorado line is standardized as far as Sodaville. Manager Tripp says this line will be ready to accommodate broad gauge cars before the Southern Pacific. Upon completion of the work the time between Tonopah and Reno will be reduced to eight hours.—J. McKane has leased half of the Quartzite fraction at Diamondfield, and is removing machinery from the Jumbo to the lease.

The Tonopah M. Co., F. A. Keith of Tonopah, general manager, will build a mill to treat ore from their own and surrounding mines.

### OREGON.

#### Baker County.

(Special Correspondence).—The Queen of the West mines have been examined by C. W. Raymond of San Francisco for Minneapolis interests, and it is probable that operations will be increased during the spring. A mill, concentrating plant, aerial tramway and compressor plant, operated by water power, are being considered and development work will be pushed. Eight men are employed in running the lower crosscut tunnel to cut the Queen of the West ledge, giving 400 feet backs. This ledge is parallel to the general system of ledges on the east slope of Cornucopia mountain at Bonanza basin and lies 2000 feet above the Union-Companion and Red Jacket ledge, owned by the Union-Cornucopia M. Co., and has been bought in by the creditors, there being a probability of its being reopened in the spring. This property is equipped with a 20-stamp mill, concentrators and slime tables. The mine, as is the case with all the mines in the district, is operated through tunnels. E. B. Seales of New York was interested. The Cornucopia district abounds in well-defined ledges of high-grade ore, carrying gold, silver and tellurium. The ores plate about 20% and the concentrates average 6%, containing \$200 to \$400 per ton gold. The extraction is a concentrating proposition; the concentrates are at present shipped to the Sumpter smelter. The district is well provided with timber and water; the altitude of the town of Cornucopia is 4700 feet and at the mines 7000 to 8000 feet; distance from Baker City by stage, 63 miles; if the proposed railroad from Baker City to Pine Valley and Homestead is constructed, the district will be of easy access and much active work will be undertaken.

Baker City, Jan. 17.

At the Snow Creek mine, near Tipton, the mill batteries have been realigned and the mortar blocks reset and the 10-stamp mill is running under charge of C. F. Raht of Sumpter. When the station is cut at the 225-foot level, the shaft will be sunk 100 feet.—Manager Field reports that the electric equipment of the Baisley mine and mill, near Baker City, has been completed. A sinking pump will be put in at level No. 3, to allow further sinking. Electricity is used for lighting the camp and underground workings and for running the hoists. Forty men are at work in mine and mill.

Shipping ore has been struck in the west drifts of the 150-foot level of the Mountain View mine at Bourne and is being sent to the Sumpter smelter, of which C. Kirchen is superintendent.

It is reported that the Sagamore mine, 14 miles west of Cornucopia, has been sold to Eastern men.—The boring for water for milling purposes at the Emma mine in the Virtue district, near Baker City, is down nearly 300 feet, without striking water. Pending water supply, the bins at mill and dump are being filled with high-grade ore.

#### Josephine County.

The Greenback Gold M. Co. and the Martha Gold M. Co., operated under one management, have added to the Greenback claims the Scenic, Vulcan, Scorpion, Yellow Dog and St. Peters, and will develop them under the superintendence of R. N. Bishop at Greenback and W. Brevoort. The Vulcan has a 5-stamp mill, and the Yellow Dog a 3-stamp. A 10-stamp mill will be put on the Scenic. Ore from the St. Peters will be brought by gravity tram to the 40-stamp Greenback mill.

#### Lane County.

A 2-stamp battery has been added to the Great Northern milling plant, Blue River district. H. C. Mabon, manager of the Great Northern Development Co., which owns the property, states that the two batteries have crushed eight to ten tons a stamp with friable ore. A Huntington mill will be used for the softer ore. Another concentrating table was put in with the last battery of stamps and another will go in with the Huntington. The main drift is in 625 feet. The lower tunnel is being driven 200 feet below the main shaft and is in 200 feet. The 1200-foot aerial tram contemplated by the management is to be connected with this tunnel.

### SOUTH DAKOTA.

The Mining Review reports that during 1904 the following mills were put in commission:

Name of Company.	Tons—	Daily Capacity.
Black Eagle.....	60	Rockford.
Gilt Edge Maid.....	150	G. A. Duncan, Galena.
Golden Crest.....	50	F. M. Strout, Mill Supt., Galena.
Homestake (increased).....	400	C. W. Merrill, Mill Supt., Lead.
Hidden Fortune.....	120	H. J. Mayham, Sec., Lead.
Horseshoe.....	350	W. L. McLaughlin, Mgr., Hot Springs.
Lundberg, Dorr & Wilson.....	60	At Ferry.
Rossiter.....	100	Bryan Rossiter, Mgr., Deadwood.

Construction was commenced on the following plants:

Name of Company.	Tons—	Daily Capacity.
Branch Mint.....	900	J. C. Hardin, Pres., Galena.
Globe.....	100	F. E. Wade, Lead.
Golden West.....	150	E. J. Kennedy, Sec., Rockford.
Ohio-Deadwood.....	100	I. B. Murphy, Mgr., Hot Springs.
Queen of the Hills.....	100	E. P. Farnham, Sec., Central City.

The following mills are contemplated and construction will be commenced early in the spring:

Name of Company.	Tons—	Daily Capacity.
Bullion.....	200	F. H. Long, 1213 Schiller Bldg., Chicago, Ill.
Columbus.....	1000	M. Thompson, Mgr., Keystone.
Deer Lick.....	150	F. M. Nash, Lead.
Eleventh Hour.....	150	J. Madril, Supt., Spearfish.
Lucky Strike.....	250	C. A. Allen, Mgr., Spearfish.
Reliance.....	300	F. W. Medbury, Deadwood.
Safe Investment.....	250	I. N. Webb, Deadwood.
Saginaw.....	100	L. P. Woodbury, Pres., Chicago, Ill.
Victoria.....	200	G. S. Jackson, Deadwood.

#### Lawrence County.

According to the Black Hills Mining Review, the gold production during 1904 for the Black Hills was:

Name of Company.	Production.
Black Eagle.....	5,500.00
Clinton and Portland.....	3,037.70
Clover Leaf.....	166,200.00
Cochran.....	3,500.00
Columbus Consolidated.....	36,000.00
Dakota.....	90,955.84
Extreme.....	2,500.00
Golden Crest.....	33,815.00
Golden Reward.....	414,190.51
Hidden Fortune.....	136,000.00
Homestake.....	4,950,558.48
Horseshoe.....	412,337.45
Imperial.....	239,800.00
Lundberg, Dorr & Wilson.....	142,000.00
Maitland, A.....	315,078.16
Monarch.....	2,208.54
National Smelter.....	45,056.00
Spearfish.....	236,000.00
Wasp No. 2.....	111,000.00
Placer.....	10,000.00
Total.....	\$7,358,137.78

### UTAH.

#### Juab County

Superintendent J. H. McChrystall of the Godiva mine at Eureka will build a concentrating mill.—The Gemini M. Co. is figuring on putting in two pumps to do away with the hoisting of water. One of the pumps may be put in on the 1000-foot level and another either on the 1600 or 1700-foot levels.—The Eagle & Blue Bell mine at Eureka, J. Creighton, superintendent, will put in a new compressor. The station on the 800-foot level has been completed and a drift will be run 150 feet to tap the main ore body. From the 800-foot level the shaft will be dropped down to the 1000-foot level before another station is cut. The mine is shipping forty tons per day.

#### Salt Lake County.

It is reported that the Boston Con., at Bingham, will put in a milling plant to work its copper-bearing porphyry. It is expected to have a capacity of 500 tons a day and to cost \$100,000. Superintendent S. S. Cates has men developing the porphyry formation.

### WASHINGTON.

#### Ferry County.

(Special Correspondence).—Superintendent W. M. O'Connell of the Ramore mine, at Park City, in the Republic district, says the tunnel in his mine is 800 feet in length and has crossed four good-sized veins, all of which carry fair values in silver-lead, gold and copper.

Republic, Jan. 16.

#### King County.

(Special Correspondence).—A big smelter, to cost \$750,000, is a possibility for Seattle. S. I. Silverman is in communication with the Seattle Chamber of Commerce and promises to erect a 400-ton plant, providing certain concessions are made in regard to a site. The smelter is designed to handle the ores from Alaska's mines.

Seattle, Jan. 16.

#### Snohomish County.

The Rainey mine, near Monte Cristo, is shipping sixty tons of ore a week to the Everett smelter, from the 100 and 200-foot levels.—An electric light plant, with capacity for 150 20-candle power lamps, has been put in at the Golden Chord mine, near Monte Cristo, by J. M. Williams. The dynamo is driven by a 12-inch Pelton wheel at the compressor house.—The Philo mine, near Monte Cristo, is equipped with a 2-hucket tram, 1800 feet long, operated by a gasoline engine, and is connected with the tram of the Pride mine, which has been leased by the Philo company and overhauled and repaired. The company intends installing an air compressor and drills.

#### Spokane County.

D. C. Corbin will build a branch standard gauge railroad from Spokane to the international boundary, where it will connect with a branch to be built to the Canadian Pacific. A 50-year traffic agreement has been made with the Canadian Pacific. The road will be called the Spokane International.

#### Stevens County.

(Special Correspondence).—A third furnace is to be added to the Northport smelter within the next month. The plant is handling 400 tons of ore daily and the additional furnace is to have a capacity of 100 tons. The company has contracted with the Copper King mine, near Chewelah, to handle all the ore it will furnish.

Northport, Jan. 15.

#### Wahkiakum County.

(Special Correspondence).—The Standard Group Marble Co., owning 200 acres of marble land near Rosburg, has opened up a new deposit of variegated marble and has ordered machinery to be installed at the quarries in the spring.

Rosburg, Jan. 16.

## FOREIGN.

### BRITISH COLUMBIA.

According to the B. C. Mining Record, the mineral production of British Columbia during 1904 was as follows:

	Ounces.	
Gold, placer.....	57,050	\$1,141,000
Gold, lode.....	256,135	5,123,000
Total gold.....	313,185	\$6,264,000
Silver.....	3,505,805	1,808,000
Copper.....	36,088,580	4,540,000
Lead.....	37,000,000	1,415,000
Zinc and iron.....		100,000
Total metallic.....		\$14,217,000
Coal.....	1,668,000	504,000
Coke.....	272,400	1,362,000
Building materials.....		550,000
Total.....		\$21,133,000

The production by districts was: Cariboo, \$500,000; Cassiar, \$520,000; East Kootenay, \$4,813,800; West Kootenay, \$6,266,600; Lillooet, \$25,000; Yale, \$4,025,900; Coast (Mainland, Vancouver Island, etc.), \$4,431,700; miscellaneous, \$550,000. Total, \$21,133,000.

#### Boundary District.

Boundary shipments during 1904 were in tons: Granby mines 543,000, Brooklyn-Stemwinder 24,000, Rawhide 2000, Mother Lode 175,800, Sunset 2800, Emma 38,000, Senator 3500, Oro Denoro 15,000, Mountain Rose 1800, Athelstan-Jackpot 4600, High Grade mines 1500, miscellaneous shipments 750; total 812,750.

The British Columbia Copper Co. at Greenwood during 1904 received 211,864 tons of ore, 2489 tons of matte and 1526 tons of blister copper. The total production of metals was: Gold, 35,911 ounces; silver, 116,685 ounces; copper, 5,201,073 pounds.

#### Kootenay District.

(Special Correspondence).—The financial statement of Manager Cronin of the St. Eugene is as follows: Total output, 12,786,860 pounds of concentrates; net value from Trail and Nelson smelters, \$130,053.24; Government bounty on 8,269,537 pounds of lead, \$62,127.94; total net value, \$192,181.18; sold in Europe, 8,692,005 pounds; net value from purchasers, \$127,410.20; Government bounty, \$29,533.20; total net values, \$156,943.91, or about \$3.37 per ton.

Nelson, Jan. 15.

#### Slocan District.

The silver-lead production in tons for 1904 for the Slocan district was: Slocan Star 2808, Ivanhoe 1405, Payne 1130, Reco 1018, Last Chance 388, Ruth 490, Blue Bird 61, Sunset 313, Mountain Con. 210, Sovereign 41, Idaho 980, Ramhler 850, Monitor 20, Cinderella-Medford 175, Red Fox 90, Antoine 60, Majestic 38, Joe Joe 33, Mercury 20, American Boy 42, Lucky Jim 201, Wakefield 420; total 10,973. The production of zinc was in tons: Lucky Jim 3000, Ivanhoe 1073, Payne 974, Idaho 32, Wakefield 160; total 5239.

#### Vancouver Island.

During 1904 the Tyee Copper Co.'s smelter at Ladysmith was in blast 267 days of twenty-four hours each, and smelted 57,450 tons of Tyee ore and 7953 tons of custom ore, 65,403 tons in all. This gives 6025.688 tons of copper matte, containing 5,120,870 pounds of copper, 179,769.19 ounces of silver, 11,088,830 ounces of gold, the total value, less refining charges, being \$831,902.41. A hoisting engine, hoiler and compressor have been put on the "X. L.," belonging to the Tyee Co. property, and a two-compartment shaft has been sunk 150 feet. E. C. Musgrave is superintendent. The main Tyee shaft is down 600 feet and will be continued till 1000 feet deep.—The Vancouver Island M. & D. Co. has put a hoisting engine, hoiler and compressor plant, and sunk a 500-foot two-compartment shaft on the Westholme. At the 300-foot level crosscuts have been driven 860 feet.

## CANADA.

#### Ontario.

The Hamilton Cataract Power, Light & Traction Co have started the two 5000-kilowatt Westinghouse generators in the De Cew falls power station in Ontario. Power is supplied from Welland canal feeders, tapped 14 miles above the power station, and at the station the water has a head of 267 feet. The generators are of the two-bearing type, direct connected to Escher-Wyss water wheels, and run at a speed of 286 revolutions per minute. They generate three-phase current at a frequency of sixty-six cycles, and a pressure of 2400 volts. The power is transmitted to Hamilton, Ontario, where it is used for lighting, street railway and manufacturing purposes. A reserve steam-driven station is at Hamilton, which contains two 1000-kilowatt Westinghouse generators. The entire station and high tension apparatus are of Westinghouse design. The company has two separate three-phase transmission lines to Hamilton, a distance of about 35 miles. The high tension apparatus is designed for a pressure of 40,000 volts, but will be operated for a time at 20,000 volts. W. V. C. Hawkins is general manager of the Hamilton company and engineer in charge.

### MEXICO.

#### Chihuahua.

The shaft on the Capazaya, near Parral, is down 310 feet; crosscutting at the 200-foot level to connect the old and new shafts is being pushed.—The electric hoist has been put in and the power turned on at El Duque shaft of the San Nicolas M. Co.—The Sierra Madre is hoisting and shipping from 300 to 350 tons of ore a week. The pumps have been working continuously since started and the mine is sufficiently unwatered to allow drifting at the 600-foot level, where high-grade ore has been found.—The prospect shaft is down 70 feet on the Salvador property.—The Capazaya, Sierra Madre, Salvador and Almacena properties are under the management of A. M. Davis, with office at No. 1 Casa de Fuentes, Parral.—H. L. Dignowity of San Antonio, G. C. Beckman, manager of the Banco Minero, and G. B. Calnan of Santa Rosalia, will tunnel and sink shafts on forty-five pertenencias in Nalca, 16 miles north of Concho, on the Mexican Central.—C. Rodriguez & Co., owners of the Cigarrera mines, near the center of the Sierra de Almoleya range, 9 miles south of Baca, on the Central Railway, between Jimenez and Parral, has a concession to build a standard-gauge railroad from Baca to its mines, the same to be started inside of six months and at least 10 kilometers built per year. They are putting in an electric plant to run the hoist and drills. The ore carries good values in gold, silver and copper.

At Guadalupe y Calvo it is reported that Superintendent J. A. Peabody will add forty stamps to the mill.

The San Francisco del Oro Mines, Ltd., of 65 London Wall, London, E. C., the Earl of Denbigh, president, and J. E. Hyslop, general manager, are working the San Francisco del Oro, near Santa Barbara, including the Sto. Tomas, Zaynas, Terreros, Las Guijas, La Tuita, La Soledad, San Francisco Nos. 1, 2 and 3, San Jose, La Coheza, La Criada and Nuestra Sonora, all containing 135 pertenencias. The deepest point is 416 feet vertical, or 427 on dip. A new tunnel is being driven, which will come 200 feet below lowest working and will be 2067 feet long. The cable tramway is 2600 meters long and is run by gravity, a small gasoline engine being used as a check. Upon arrival at the terminal of the cable, the ore is passed over grizzlies, separating the fine from the coarse, the latter moving on by gravity to sorting tables, where it is cleaned. In loading, the wagons that transport the ore to the neighboring railroad are stopped under the bridges, to which are attached chutes, the average time of loading being one and one-half tons per minute. At present the wagons go to the Molinos station on the Parral & Durango railroad, and thence to the custom smelters. At this time the mine is shipping from 130 to 150 tons daily. The company will erect a plant for wet concentration, magnetic separation, the slimes and tailings then to be mixed with siliceous ores and treated by lixiviation. A railway is contemplated, which will tap either the Parral & Durango railroad or the Mexican Central railway.

#### Durango.

The Miller-Sibley M. & S. Co. has stopped work in its mines at Topla.—The Amazon G. M. Co. of Chacala is putting in a blast matting furnace with which to handle the copper-lead-hismuth ores. It was found that in the reverberatory furnace, which has been in operation for some time, the oxidation and consequent loss of the himuth was beyond control.

#### Guanajuato.

The Guanajuato R. & M. Co. will build a 160-ton stamp mill at the Cata mine and a 500-ton cyanide mill, near Guanajuato, piping the pulp 1½ mile from mill to cyanide plant. C. L. Kutz is president, H. H. Filley, engineer in charge, and C. W. Van Law, manager.

#### Oaxaca.

L. G. Teruel, president of the Oaxaca & Ejutla Railway, has obtained a concession to put in a metallurgical and smelting establishment in the city of Oaxaca or in Ocatlan or Ejutla, as he may elect. The capacity of the furnace shall not be less than 100 tons daily. The machinery, apparatus, etc., required may be imported free of duty for once only. The construction of the establishment must begin within one year from December 23, 1904, and must be completed within two years of the same date.

Mining machinery is to be purchased for the Baldomera at Ocatlan by C. H. Hamilton.

It is reported that the Predilecta and Tetraxini mines, near Ejutla, will be bought by the El Oro M. Co.

#### Sinaloa.

M. M. Stewart of San Luis Potosi has an eight-year option and lease on the property of H. Amador in Sinaloa, and has ten stamps dropping and three concentrators running; also compressor for drilling and unwatering the mines. All motive power is water.—The Fernando M. Co. of Fernando has completed its 30-stamp mill.—The Toro M. Co. of Canelles has suspended

operations.—It is reported that the San Juan M. & D. Co. will build a 100-ton smelter in Culliacan.

Machinery has been ordered for the San Fernando G. M. Co., near Altata, of which C. W. Pritchett of Denver, Colo., is manager, and plans are being made for a large reduction plant.

The owners of the Alianza and Morelos mines in the Badiraguato district will erect reduction works near the mines. The machinery for the projected plant is now being made in the Sinaloa foundry in Mazatlan. The owners are A. Sanchez, H. E. Gaxiola, C. Vilderrain and E. Vasquez.

#### SONORA.

(Special Correspondence).—The Sonora Bonanza M. Co. at Cananea will sink three shafts on their copper ledge. R. McCune has charge. Brally, Wallace & Dressel report a body of copper and silver ore in the drift on the 100-foot level in their mine near Janoverachi. Cananea, Jan. 14.

A. G. Pace, C. Laux and J. Sattory are prospecting and developing the San Juan and Reina Prieta veins at San Juan Grande, 15 miles from Soyopa, in the Ures district. They are also working placer deposits in the Sibichicori and Rebreo canyons. F. H. Seymour of Torres is interested.

A. W. Morris, superintendent of the Golfo de Oro M. Co. at La Concentraci6n, has ordered a hoisting engine for the new shaft on the Mina de Oro, down 100 feet. The ore is treated in a 10-stamp mill and cyanide plant.

At La Dura a Lidgerwood hoist has been put up by La Dura M. & M. Co. upon the new vertical double-compartment shaft at La Gloria, which is 800 feet deep. It can work to a depth of 1200 feet and has a hoisting capacity of six tons 6 feet per second. D. P. Schabrum is manager. C. W. Phillips of Sonora has taken over the Tres Naciones, Flora and Bellamanda in the Magdalena district, near Brisca, which have been owned by the Canizares Brothers of La Calera. He will build a 10-stamp mill and sink a working shaft on the Tres Naciones.

Richardson Bros. Co. of Los Angeles, Cal., will construct a railway from Guaymas on the Gulf of California to Torin on the Yaqui river, thence up that river to La Dura, across to La Bufa and Trinidad. They own La Bufa mines and a 30-ton custom smelter at La Bufa.

#### NICARAGUA.

The United States Consul reports considerable activity among the mine operators north of Bluefields in the installation of new machinery and the application of modern methods, which promises to increase greatly the output of gold in this region. The Bonanza and Lone Star mines in the Tunkey district are adding cyanide plants for the extraction of gold from tailings. These are expected to be in operation. It is estimated that 50% of the gold is lost in the tailings, and it is believed that this process will save 70% of what has heretofore been thrown away. The Siempre Viva M. Co. is installing an electrical plant, to be run by water power from Piz Piz falls, for the operation of the mill and working of the mines as well as the cyanide process, the total expense being \$100,000. The Constance, near the Siempre Viva mines, is completing a 10-stamp mill, which will shortly be in operation. The La Luz and Los Angeles mines, in the Cuicuina district, are expending \$30,000 in developing their water power and in other improvements. The Topaz M. Co., in the Mico district, above Rama, intends installing cyanide and electrical plants. The placer mines in Cuicuina district are making a good showing, and there is every prospect that by the end of another year the eastern coast of Nicaragua will produce a noteworthy output of gold.

#### PERU.

A. H. Kennedy and G. F. Hutchins of Mexico are constructing the 1000-ton smelter for the Cerro del Pasco mine, being erected under contract with M. P. Connel. The Cerro del Pasco district smelter is east of the Western Cordilleras of the Peruvian Alps, 265 miles from Callao, and is reached over the Peruvian Central and Cerro del Pasco Railroads. The latter was officially received by the Government on July 28, 1904. The road has a mean elevation of 13,000 feet at Cerro del Pasco, reaching 14,200 feet. A branch is being built to the company's coal mines, north of the mine. A. W. McCune is general manager at Lima and Jas. MacFarlane is superintendent of mines at Cerro del Pasco. The mines were worked for silver in 1630. The ores carry gold, silver, copper and cobalt, silver values decreasing and copper increasing with moderate depth.

#### Personal.

C. A. FOHRMAN is superintendent of the Caso Diable G. M. Co. at Bishop, Cal.

W. B. LEWALD is manager of the Ohio-Pennsylvania mines at Argentine, Colo.

L. LINDSAY of Cananea, Mexico, is in Los Angeles, Cal., buying mining machinery.

P. McGERRY, manager of the Comstock group, near Granite, Or., is at Baker City, Or.

D. LANDSBERG has been made foreman of the Treadwell mines, Douglas Island, Alaska.

J. L. SHEPERD of Nogales is manager of the Realito Copper M. Co. at Realito, Sonora, Mex.

G. W. PHILLIPS is manager of the Calera M. Co., 12 miles west of Minaca, Chihuahua, Mexico.

J. W. DIXON of Dunlevy, County Wicklow, Ireland, is examining mines in Tuolumne county, Cal.

F. FAY of Keystone, South Dakota, is in Cananea, Mexico, in employ of the Cananea Con. C. Co.

GEORGE W. MYERS, representing the Chrome Steel Works on the Pacific coast, has gone to southern

California and southwestern Nevada from San Francisco, Cal.

H. C. McFERNY, superintendent of the Eureka Con. at Eureka, Nev., has been visiting San Francisco, Cal.

G. E. ALEXANDER of Marysville, Mo., has accepted the position as metallurgist for the Oro M. Co. at Oro, Ariz.

J. MADILL is superintendent of the Eleventh Hour G. M. Co., at Ragged Top, 8 miles west of Lead City, South Dakota.

A. S. DWIGHT, manager of the Cananea Con. Copper Co., has returned to Cananea, Mexico, from a trip to New York.

H. C. BELLINGER is superintending the reconstruction of the Yampa smelter and United States smelter at Bingham, Utah.

B. F. BOGENREIF of Hinton, Iowa, and P. P. Scott of Romsen, Iowa, have been examining the Vulcan mine at Silver Plume, Colo.

G. ADAMS of Eureka, Utah, is superintending the development of the Surprise group, near Shem, Washington county, Utah.

R. C. COY of Chicago, vice-president of the Libertad M. Co., has been examining the company's mines at Libertad, Sonora, Mex.

H. J. BEEMER of New York, president of the Amalgamated Gold Mines Co. of Quartzsite, Arizona, is superintending work at the mines.

R. HOWARD has succeeded J. R. Sharp as superintendent of the Sunnyside coal mines of the Utah Fuel Co. at Sunnyside, Carbon county, Utah.

F. H. JOHNSON, who has been manager of the mining department of the Fulton Iron Works, San Francisco, Cal., for several years, has resigned owing to ill health, and will sever his connection with the company February 1st. Mr. Johnson expects to spend the next two or three months in the southern part of California and Arizona recuperating.

#### Books Received.

Verily a little knowledge is a dangerous thing, especially if the possessor thereof attempts to impress the unlettered man with the profundity of his studies. In "Secrets of the Rocks" S. M. Frazier gorges us with a non-assimilable mass of undigested facts and theories gleaned mainly from books of the past generation, most of whose propositions have long since been refuted. The expressed object of the book is to give the practical prospector an insight into the wonders of science, combining it with instructions as to intelligent prospecting. Its real effect is to muddle the mind with unproved theories and present a few facts regarding outdoor life that an amateur camper might require. His definitions of scientific terms are loose and indefinite, his compiled facts are illogically and poorly arranged, the treatment is rambling and inconvenient. The book contains little that could not have been written by one who had never seen a rock. Undue prominence is made of the importance of the historical sequence of rock formation as an aid to prospecting. He states that "the primary source of gold is in granite and associate rocks, its presence being due to a coagulation of the small particles in its primary sources. Granite is a close, compact body of fragments of other stony matter." The ponderousness of "science" is lightened by legends and stories of lost mines and wonderfully lucky strikes, a great love for scenery, and accompanying flowery language is displayed. One is especially impressed with the importance of the "trappean" rocks in the "process of world building." If the 432 pages were concentrated to four pages, the prospector might find it interesting for an hour's reading. Its chief recommendation is that it gave some deserving printer a job. It is published by Hall & Williams, 1742 Stout street, Denver, Colo.

"A Treatise on Metamorphism," by C. R. Van Hise, is the latest production of this noted geologist. This monograph, of 1286 pages, will undoubtedly be valuable as a standard reference book for the geologist for many years to come. In following up his object of organizing the examples of metamorphism under the laws of physics and chemistry, the author has written a careful treatise, including descriptions of most of the geological forces active since the formation of the earth. As a text book for students of geology it is good in showing how the present conditions of the earth are the result, not of cataclysms, but of the accumulative effect of chemical energy, gravity, heat, and light, together with gaseous and aqueous solutions and organisms. An application of the latest principles in physical chemistry is lacking and, in view of the rapid strides being made in this science, Prof. Van Hise's assumptions may have to be revised. The chapter on the various changes taking place in the belts of weathering, cementation and anamorphism are valuable in giving reasons for different structures. It is to be regretted that the igneous rocks could not have been discussed, as well as the sedimentary rocks. Much of the discussion on ore deposits has previously appeared elsewhere. On the whole, the book is an excellent compilation. It reorganizes and brings many widely scattered facts and theories into compact form. It is to be regarded as a forerunner in this class of work, leaving much to be done by future geologists, especially in the line of laboratory work in verifying certain hypothetical chemical reactions. To the student of rocks and rock-forming minerals, it apparently does not accomplish what was expected as an aid in rock identification. The chapters on specific mineral metamorphism will undoubtedly be valuable and could be made more accessible if published without the great shell of unverified speculation regarding causes. It seems to be lacking in data by which the origin of the metamorphosed rock, especially of intrusives, can be determined. The volume is

listed as Monograph XLVII of the United States Geological Survey, and may be obtained for \$1.50 upon application to the Director, at Washington, D. C.

The United States Geological Survey, under title of "Mineral Resources of the United States," has issued "The Production of Gold and Silver in 1903." The total statistics of the production of gold and silver for 1903 are furnished, as heretofore, by the Director of the Mint, but the statistical canvass made by the United States Geological Survey resulted in some differences in the distribution of the product among the several States and Territories. During the calendar year 1903 the United States produced 3,560,000 fine ounces of gold, valued at \$73,591,700, a decrease of \$6,408,300, or 8.01%, as compared with the production of 1902. Of the twenty-one States and Territories yielding gold in 1903, eleven showed an increase in production, Nevada leading with an increase of \$492,700, or 17.02%. Alaska, which led in increase in 1902, was second in 1903, with an increase of \$268,900. Kansas and Tennessee, with productions valued, respectively, at \$9700 and \$800, reported for the first time in 1903. The other States and Territories showing gains in 1903 were as follows: Arizona, \$245,300; Utah, \$102,900; Idaho, \$95,400; Montana, \$38,300; Virginia, \$10,400; Washington, \$7700, and Alabama, \$1900. The greatest decrease in production in 1903 was in Colorado, where the production fell off \$5,928,600, or 20.82%. California was second in amount of decrease in 1903, falling off \$687,600. Decreases were also noted in the following States and Territories: Oregon, \$526,500; New Mexico, \$286,500; South Dakota, \$138,700; Georgia, \$35,800; Wyoming, \$35,200; South Carolina, \$21,200; North Carolina, \$20,200, and Maryland, \$2000. The silver yield of the United States for 1903 amounted to 54,300,000 fine ounces, with a coining value of \$70,206,060 and a commercial value of \$29,322,000, a decrease in quantity of 1,200,000 fine ounces, or 2.16%. Of the twenty-one States and Territories producing silver in 1903, eleven showed increased production. Nevada, which led in increase of production of silver in 1902, held the same position in 1903, showing an increase of 1,304,300 fine ounces, or 34.82%. This great increase is due to further developments in the rich Tonopah district in Nye county. The following States and Territories also showed gains in production in 1903 over 1902: Idaho, 652,600 ounces; Utah, 365,100 ounces; Arizona, 344,000 ounces; Alaska, 51,600 ounces; California, 30,700 ounces; Oregon, 24,700 ounces; Texas, 8200 ounces; Virginia, 3600 ounces, and Tennessee, 700 ounces. Kansas reported silver for the first time in 1903, having a production of 97,400 ounces. The greatest decrease in the production of silver in 1903 was in Colorado and amounted to 2,685,800 fine ounces. Alabama, which reported 100 fine ounces of silver in 1902, reported no production in 1903. Other decreases were as follows: Montana, 601,500 ounces; Washington, 324,500 ounces; New Mexico, 276,500 ounces; South Dakota, 119,000 ounces; Michigan, 60,800 ounces; North Carolina, 9900 ounces, and Wyoming, 4800 ounces. The total value of the production of the precious metals by the United States in 1903 (silver at commercial value) amounted to \$102,913,700, a decrease of \$6,501,300, or 5.94% from the yield of 1902.

#### Commercial Paragraphs.

THE S. H. Harmon Lumber Co. have removed their sales office to 328 Montgomery street, San Francisco, Cal.

H. C. MORTIMER JR. has joined the New York office staff of the Crocker-Wheeler Co. He will assist F. B. DeGress, manager of that office, and will succeed A. J. Thompson.

THE Clyde Iron Works, Duluth, Minn., have a valuable testimonial from one of the contractors constructing an eight-story fire-proof hotel at Baltimore. "The Campbell concrete mixer made a record of 205 batches, mixed in nine hours with a one-quarter yard machine." The use of concrete mixers is increasing constantly, and the Campbell mixer manufactured by the above concern is one of the leading makes.

MANAGER CRANK at Johannesburg, South Africa, recently installed a Blaisdel 40x8-foot class A excavator, with conveying system, and a Blaisdel 40-foot class Z distributor at the Robinson Gold Mines, Ltd. He reports that on December 3rd General Manager Meine, R. Matthews, cyanide manager of the Robinson, N. Wilson, chief mechanical engineer for the East Rand Proprietary Mines, together with other cyanide managers and engineers, inspected the work. He states that it was found that the guaranty that it would discharge a vat at the rate of 100 tons per hour, on not exceeding 15 H. P., exceeded this capacity by 100% and reduced the horse power 25% and claims that, as the cost of electrical horse power at the Robinson does not exceed 1 cent per horse power per hour, the per ton cost of handling at 200 tons per hour is .000685 and at 100 tons per hour is .00113. Mr. Crank states that all present were much pleased with the showing made by the machine.

THE Masurite Explosive Co. write that the delays to which their shipments have been subjected in the past two years have been unavoidable and much regretted by them. Their material being new in every sense, the erection of a plant for the successful manufacture has been a more prolonged matter than at first anticipated. Several times it has been necessary to discard certain pieces of machinery and plans of manufacture. Sufficient local trade from their immediate vicinity took up the output of their factory in its incomplete state, and they have been compelled to defer shipments to the Pacific coast until they could manufacture a sufficient surplus to take immediate care of orders from the Pacific coast. They now feel that they have about overcome all possible difficulties, and expect in the near future to be able to fill all of the orders they now have on hand, and make such further arrangements as will provide a convenient source of supply for all users of their material anywhere and everywhere. Geo. W. Myers, San Francisco, Cal., is their Pacific coast representative.

## Trade Treatises.

The Midvale Steel Co.'s catalogue of wearing parts and smelter castings gives sectional views of many of their makes. The Pacific coast office is at 220 Market street, San Francisco, Cal.

Coal mining machinery in all its multiple forms and designs is discussed elaborately in Catalogue No. 52, which is full of interesting data and description, including pneumatic haulage. It is issued by the Ingersoll-Sergeant Drill Co., and will be sent to any address.

Catalogue No. 12 of the Sturtevant Mill Co., Harrison Square, Boston, Mass., is devoted to rock and ore reducing machinery, and beside much that appears in that firm's effective advertisements there is a wealth of detail regarding their roll jaw crushers, balance rolls, screens, blowers, engines and boilers that makes the catalogue a valuable supplement thereto. The treatise deserves the distinction it has received of being copyrighted, but will be sent to any address on request.

From an artistic point of view, the brochure on the Sturtevant Leverless Automatic Motor Car, from the Sturtevant Mill Co., Harrison Square, Boston, Mass., is the finest trade production received this year. Typographically, it is beyond criticism, the reading part of it is finely arranged and the arguments used are most convincing. Anyone who has anything to do in any way, present or prospective, with an automobile should see this booklet, each page of which deserves framing as a work of art.

## Latest Market Reports.

SAN FRANCISCO, January 20, 1905.

### METALS.

**SILVER.**—Per oz., Troy: London, 27½d (standard ounce, 925 fine); New York, bar silver, 60½c, refined (1000 fine); San Francisco, 60½c; Mexican dollars, 51c, San Francisco; 47½c, New York.

**COPPER.**—New York: Standard, \$15.50; Lake, 1 to 3 casks, \$15.37½@15.50; Electrolytic, 1 to 3 casks, \$15.37½; Casting, 1 to 3 casks, \$15.25. San Francisco: \$16.00. Mill copper plates, \$17.00; bars, 18@24c. London: £68 12s 6d spot per ton.

According to the official statistical circular issued by Jas. Lewis & Sons of Liverpool, the total visible supply of copper in the world Jan. 3, 1905, was 16,734 tons, as against 22,935 tons Jan. 1, 1900, 28,921 tons Jan. 1, 1901, 22,063 tons Jan. 1, 1902, 16,540 tons Jan. 1, 1903, and 13,505 tons Jan. 1, 1904. The present outlook for the metal, both at home and abroad, is good. The producers here have been enabled to gain but little upon the demand. New districts are looked to to increase the output, but a copper mine can not be developed and equipped for large production short of several months, and it often requires several years.

**LEAD.**—New York, \$4.70; Salt Lake City, \$3.50; St. Louis, \$4.12½; San Francisco, \$4.50, carload lots; 4½c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5½c; pig, \$4.85. London: £12 17s 6d per long ton.

**SPELTER.**—New York, \$6.35; St. Louis, \$6.25; London, £24 17s 6d per ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

**TIN.**—New York, pig, \$29.25@29.75; San Francisco, ton lots, 30c; 500 lbs., 30½c; 200 lbs., 30½c; less, 31c; bar tin, 32½@35c. London, £131 5s spot.

**PLATINUM.**—San Francisco, crude, \$18.50 per oz.; New York, ingot, \$19.50 per Troy oz. Platinum ware, 75@82c per gram.

**QUICKSILVER.**—New York, \$40.00@41.00, large lots; London, £7 15s; San Francisco, local, \$39.00 per flask of 75 lbs.; Denver, \$45.00.

**BABBITT METAL.**—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 31½c; Eclipse, 35c.

**SOLDER.**—Half-and-half, 100-lb. lots, 19.50c; San Francisco, Plumbers', 100-lb. lots, 16.25c.

**ZINC.**—Metallic, chemically pure, per lb., 50c; dust, per lb., 10c; sulphate, per lb., .04c.

**NICKEL.**—New York, 55@60c per lb.; ton lots, 40@47c.

**ALUMINUM.**—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31@34c.

**ALUMINUM.**—No. 1, 99%, small lots, 37c per lb.; 100 lbs., 35c; 1000 lbs., 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

### STRUCTURAL MATERIALS.

**IRON.**—Pittsburg, Bessemer pig, \$16.85@17.10; gray

forge, \$15.85; San Francisco, bar, 3c per lb., 3½c in small quantities.

**STEEL.**—Bessemer billets, Pittsburg, \$27.00; open hearth billets, \$27.00; San Francisco, bar, 7c to 12c per lb.

**WHITE LEAD.**—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, ½c per lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

**LUMBER.**—(Retail): Pine, ordinary sizes, \$24.00@25.00; extra sizes higher; redwood, \$28.00@30.00; lath, 4 feet, \$4.50@5.00; pickets, \$21.00; shingles, \$2.50 for No. 1 and \$2.25 for No. 2; shakes, \$13.50 for split and \$15.00 for sawed; rustic, \$28.00@35.00.

**NAILS.**—This week the basic prices are: Wire, \$2.77; Cut, \$3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, \$3.35; Cut, \$3.55; 10d to 16d, Wire, \$3.45; Cut, \$3.35; 8d, Wire, \$3.50; Cut, \$3.50; 6d and 7d, Wire, \$3.60; Cut, \$3.60; 4d and 5d, Wire, \$3.70; Cut, \$3.70; 3d, Wire, \$3.85; Cut, \$3.85; 2d, Wire, \$4.10; Cut, \$4.10. Special rates for carload lots.

**LIME.**—Santa Cruz, \$1.25 country, \$1.25 city per bbl.

**CEMENT.**—Imported, \$2.15@2.65 per bbl.; California, carload lots, \$2.10 f. o. b. at works; small lots, \$2.40 per bbl. in sacks, 4 sacks to bbl., 10c for each sack returned.

### GENERAL SUPPLIES.

**ANTIMONY.**—New York, Cookson's, 8½c; Hallett's, 8½c; San Francisco, 1000-lb. lots, 9c; 300@500-lb. 9½c; 100-lb. lots, 10½c.

**OILS.**—Lined, boiled, bbl., 55c; cs., 60c; raw, bbl., 53c; cs., 54c; Lucol oil, boiled, bbl., 50c; cs., 55c; raw, bbl., 48c; cs., 53c. Kerosene—Pearl, per gal., 19c; Astral, 19c; Star, 19c; Extra Star, 22c; Eocene, 21c; Elaine, 25c; Water White, in bulk, 12½c; Mineral Seal, iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Mineral Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 16c; do., cs., 22½c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19½c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 63c; Bleached, do., 57c; Whale Oil, cs., 52@57c.

**POWDER.**—F. o. b. San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1\*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1\*\*, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2\*\*, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2.00 per keg.

**CAPS.**—3x, \$5.50@6 per 1000; 4x, \$6.50@7; 5x, \$8@8.50; Lion, \$9@9.50, in lots not less than 1000.

**FUSE.**—Triple tape, \$4.00 per 1000 feet; double tape, \$3.50; single tape, \$3.10; Hemp, \$2.75; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 and up.

**CANDLES.**—Granite 6s, 16 oz., 40s., 11c per set; 14 oz., 40s., 9½c.

**CHEMICALS.**—Cyanide of potassium, 98%-99%, jobbing, 23@24c per lb.; carloads, 23@23½c; in tins, 30c; soda ash, \$2.00 per 100 lbs.; hyposulphite of soda, 3@3½c per lb.; caustic soda, in drums, 3@3½c per lb.; Cal. s. soda, bbls., \$1.10@1.20 per 100 lbs.; sks., 90c@1.00; chlorate of potash, 12@13c; nitrate of potash, 6½@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2½@2¾c; flour sulphur, French, 2½@—c; alum, \$2.00@2.25; California refined, 1½@2c; sulphide of iron, 8c per lb.; copper sulphate, 5½@5¾c; chloride of lime, spot, \$2.50@2.75; sulphuric acid, in carboys, 66% B, 1¼@2c per lb.; nitric acid, carboys, 8c per lb.

**BORAX.**—Concentrated, 6@7c per lb.; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

**BONE ASH.**—Extra No. 1, 5@6c per lb.; No. 1, 4@5c.

**LITHARGE.**—Pure, in 25-lb. bags, 8@9c per lb.

**MOLYBDENUM.**—Best, \$2.75 per lb.

**CHROMIUM.**—90% and over, per lb., 80c.

**PHOSPHORUS.**—American, per lb., 70c.

**SILVER.**—Chloride, per oz., 90c@1.00; nitrate, 55c.

**MAGNESIUM.**—Pure, N. Y., \$1.60.

**MANGANESE.**—Per lb., \$2.75.

**SODIUM.**—Metal, per lb., 50c.

**URANIUM.**—Oxide, per lb., \$3.50.

**MERCURY.**—Bichloride, per lb., 77c.

**TUNGSTEN.**—Best, per lb., \$1.25.

**FIRE BRICK.**—Domestic, carloads per 1000, f. o. b., factory square, \$25.00; soap and split, \$22.50; arch and wedge, \$27.50; skewback, \$30.00; circle, \$32.00.

**FIRE CLAY.**—Domestic, per ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, \$8.50.

## New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following U. S. patents issued to Pacific Coast inventors:

FOR WEEK ENDING JAN. 10, 1905.

779,403.—JOURNAL BOX—D. Allen, Los Angeles, Cal.  
779,829.—STEP LADDER—W. M. Anderson, Santa Paula, Cal.  
779,682.—VEHICLE—J. E. Armstrong, Santa Cruz, Cal.  
779,755.—CAR VENTILATOR—J. E. Armstrong, Santa Cruz, Cal.  
779,831.—HAT FRAME MACHINE—D. D. Beatty, Grass Valley, Cal.  
779,831.—STAMP MILL MORTAR—M. P. Boss, S. F.  
779,908.—HAND TRUCK—E. J. Bryan, Riverside, Cal.  
779,764.—DRAPERY CORDS—C. A. Burns, S. F.  
779,826.—SOLDERING MACHINE—A. Cerruti, S. F.  
779,643.—SCALE—J. C. Dixon, Hanford, Cal.  
779,915.—RIBBON HOLDER—S. P. Doane, Sacramento, Cal.  
779,773.—FLOOR SWEEPER—Dunaway & Melander, Tacoma, Wash.  
779,917.—DOOR CHECK—O. Ellingen, Santa Barbara, Cal.  
779,693.—PROCESS—F. Ephraim, S. F.  
779,700.—PISTON ROD PACKING—C. P. Fogh, Wadsworth, Nev.  
779,812.—GAS GENERATOR—F. J. Foveaux, Alameda, Cal.  
779,927.—NECK STALL—A. J. Griffith, St. Helena, Cal.  
779,648.—SCRAPER—L. B. Hammond, Portland, Or.  
779,782.—DREDGER—Henderson & Peake, Oroville, Cal.  
779,600.—BILGE BLOCK—J. Hickler, Pasadena, Cal.  
779,783.—CHEESE CUTTER—M. B. Irvine, Longbeach, Cal.  
779,945.—HARNES HOOR—L. E. Johnson, Fresno, Cal.  
779,719.—CAN TESTING MACHINE—P. Kruse, Astoria, Or.  
779,720.—VOLTAGE REGULATOR—O. M. Lacey, Hanford, Cal.  
779,721.—HAMMER—A. E. Leech, Fulton, Cal.  
779,615.—SAND WASHING MACHINE—W. B. Martin, Seattle, Wash.  
779,955.—MORTISING MACHINE—A. W. Miller, Riverside, Cal.  
779,437.—SCATCH BLOCK—G. Nettie, Leaburg, Or.  
779,732.—SCALE GEAR—J. P. Newell, Portland, Or.  
779,854.—MECHANICAL VENTILATOR—E. C. Northrup, San Jose, Cal.  
779,622.—BEDSTEAD—L. P. Pleyer, Seattle, Wash.  
779,964.—RAILWAY TRACK—J. W. Porter, Los Angeles, Cal.  
779,809.—GARMENT—L. C. Sherrick, Lemon Grove, Cal.  
779,888.—TILING—J. Singer, Los Angeles, Cal.  
779,886.—SOLDERING—G. H. Stewart, Los Angeles, Cal.  
779,887.—METAL PLATE—G. H. Stewart, Los Angeles, Cal.  
779,888.—CONDENSER—J. Todd, Seattle, Wash.  
779,892.—MECHANICAL VENTILATOR—W. D. Watkins, San Jose, Cal.  
779,893.—SIGNALLING—W. D. Watkins, San Jose, Cal.  
779,981.—DRAPER—J. C. White, Marysville, Cal.  
779,679.—BLOTTER—E. M. Wilson, Adin, Cal.  
779,680.—STAPLE SETTER—F. Wiseman, John Day, Or.

## Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

**VOLTAGE REGULATOR.**—No. 779,720. Jan. 10, 1905. O. M. Lacey, Hanford, Cal. The object of this invention is to provide an apparatus by which the voltage of a current of electricity may be constantly and automatically regulated to any desired point. This is effected by a fluid pressure acting in opposite directions upon pistons of different area, the flow of the fluid being controlled by valves actuated directly by the movements of a voltmeter, and the movement of the piston is transmitted directly to the rheostat or other controlling device. There are details of construction adapted to bring about the desired result.

**RECIPROCATING HAMMERS.**—No. 779,721. Jan. 10, 1905. A. E. Leech, Fulton, Cal. This invention relates to a reciprocating or power hammer and means for operating the same. It comprises an improved reciprocating hammer having in combination a base with an anvil block or pillar at one end, a vertical standard at the opposite end and intermediate vertical guides fixed to the base. There are braces by which a die holder or anvil is fixed to the block and the standard, the central block, the central guides and the oppositely fixed standards together and with the base. A handle handle fulcrumed in the standards passes between the guides. There are other details of construction which render the device a distinct improvement in the art and an efficient machine for the purposes required.

**PISTON ROD PACKING.**—No. 779,700. Jan. 10, 1905. C. P. Fogh, Wadsworth, Nev. This invention relates to improvements in packings for piston rods and the like. Its object is to devise a packing particularly adapted for ice machines and marine engines, which will be durable, form a vapor tight joint and which will be self-adjusting and self-oiling. By this improvement a true half joint packing results so that no undue strain is put on the packing, no matter if the rod should operate out of its normal line.

**ATTACHMENTS FOR SEWING MACHINES FOR PRODUCING DRAPERY CORDS.**—No. 779,764. Jan. 10, 1905. C. A. Burns, San Francisco, Cal. This invention consists in a device for forming a tubular flexible fabric and inserting a continuous core at a single operation, said device comprising a fixed exterior tube, a segment of smaller diameter than the interior of the tube, a radially disposed plate projecting between the edges of the segment, said plate having a divergent lower end forming a channel for a core cord, a mechanism to advance the material and return its edges and stitch-forming mechanism for uniting the meeting edges of the material.

**VEHICLE.**—No. 779,682. Jan. 10, 1905. J. E. Armstrong, Santa Cruz, Cal. This invention consists in the combination with the wheel axles and body of a vehicle, of two yoke-shaped levers fulcrumed intermediate of their ends to the vehicle body, with their inner ends continually and substantially central beneath the body, a spring having its ends supported by the fulcrum points of the levers and its central portion underlying and supporting the inner ends of both levers, said levers having the outer ends diverging and bent downwardly and swinging links by which said outer ends are connected with the axles or bolsters.

**DRAPERS.**—No. 779,981. Jan. 10, 1905. J. C. White, Marysville, Cal. This invention relates to improvements in drapers for grain elevators, headers, harvesters and the like, and its object is to provide a simple, economical and novel form of lateral reinforce where the draper cloth or canvas may be protected against wear due from constant contact with the guides in which the edges of the draper run. It consists in various details of construction adapted to bring about the desired result.

## Improved STEEL PIPE

## TANKS

Tanks Shipped K. D.

## Tallerday Manufacturing Co.

DOLGEVILLE, LOS ANGELES COUNTY, CALIFORNIA.

THE TALLERDAY PATENTED STEEL ROLLING MACHINE rolls pipe from 4 inches diameter up to any required size, in 10-foot lengths, from 20-16-14 gauge steel. The advantages of pipe in 10-foot lengths instead of the ordinary 30-inch lengths are obvious—smooth interior increases carrying capacity and decreases friction. Less joints add strength and increase the life of the pipe. One seam in a 20-foot length instead of eight as in ordinary pipe. Use the improved Tallerday Pipe and you will never be satisfied with other makes. Write for Catalogue and Prices.

## The Caving System of Mining.

The caving system of mining is employed chiefly in the Minnesota and Lake Superior iron regions. Under certain conditions the system is also applicable to other metal mines, but it is only of late that attempts have been made in this direction in the West, probably due largely to the decided innovation in methods which it represents, and partly due to the general unfamiliarity with this sort of mining. Mine superintendents who have always handled their mines by applying the various schemes for timbering and filling, commonly known to metal miners, do not at first take kindly to this new idea of the iron men, yet the fact that the caving system is successfully employed in the iron region, and has been in use long enough to prove its adaptability and usefulness over other and far older methods, is a strong recommendation in its favor. There are several methods of applying the caving system, which vary with the physical conditions under which the mine is operated. In most metal deposits the banging wall country is either too hard and firm or too soft to render the employment of caving successful and safe.

Consolidated California & Virginia Mine, Virginia City, Nev. (See Page 54.)

The object of mining by the caving system is to reduce the expenses of mining while affording every protection to the miners and securing all the ore. The latter is not always possible in metal mines, and it then becomes a question whether it is more desirable from the commercial point of view to lose a certain percentage of the ore or to employ a timber system at increased cost per ton while recovering all the ore. This is a matter for the manager to determine. In blocking out ore for stoping, all the dead and preparatory work must be charged against the ore eventually removed, and the

loss of a large tonnage of ore brings the cost of preparatory work per ton of the ore actually extracted to a considerably higher figure. If \$5000 is spent in preparations to make available 50,000 tons of ore, the estimated cost is 10 cents per ton for this preparatory work, but if only 40,000 tons are recovered from this block of ore, owing to unexpected collapse, or other unforeseen difficulty, the cost per ton of the preparatory work is 12.5 cents per ton. The difference in cost between the method employed which resulted in this loss of ore and another method which would have made it possible to have removed all of

the ore may have been as much as 50 cents per ton. Then on the 40,000 tons removed the saving would have been \$20,000. If the ore lost would not net more than this sum, it looks like good business to employ the system which resulted in the greatest ultimate profit. In these days, however, no mine superintendent likes to lose ore which he had planned to get, and he usually devises some method of recovering at least a portion of the lost ore, and then makes such changes as seem necessary, to make the removal of other blocks in the future more complete. This may not necessitate a complete change of system, but the manner of applying it may be changed to advantage. The experience gained in the former operation will usually suggest some other method of attack, and a repetition of the premature cave with consequent loss of ore may be avoided. In many mining regions commercial considerations have compelled mine superintendents to abandon old-time methods for those which were so different from the ordinary practice as to meet with little favor at first, but when their adaptability has been proven others have accepted them as a desirable change from former practices and gladly adopted them.

IN Germany the coal miners have struck, involving many kindred trades and those depending upon the output of the mines for fuel. It is stated that 300,000 men are involved and it is said to be the most serious industrial difficulty which the government and the country at large has ever been called upon to meet. Thus far there seems to be no difficulty in preserving order, but unless the differences between the miners and operators are promptly adjusted serious consequences are feared.

THE proposition often made, that of filling stopes with tailings from the mills, which are carried into the mines by means of water, is in actual practice in some mines in Europe—in Silesia and Westphalia—but it is doubtful if this practice is suited to wet mines. If the tailings could be controlled and prevented from passing through small spaces, such as commonly occur between lagging, and in many other places in the timbering, it might be available, but the means of doing this without extraordinary expense unsuits it to use in most places. In a wet mine there would be the ever present tendency to run, thus forming a menace to the lives of the miners. It would seem that this use of tailings in a wet mine might result in a run of this fine filling, something akin to the "mud rushes" of the diamond mines of South Africa. In a dry mine, after the water has been drained from the wet material, the danger from a run would probably be lessened to the minimum. The angle of dip of the vein would also probably have an important bearing on the behavior of a mass of sand thus introduced to mine workings. On the whole, at this time the employment of tailings as filling in mine stopes will not meet with favor in America.

## Relation of Dikes to Ore Deposits.

From a careful study of the description of the ore-bearing veins of Cripple Creek district in Colorado, written by Messrs. Lindgren and Ransome, an abstract of which appears elsewhere herein, it is evident that the association of the ore with phonolite and basalt dikes is merely incidental, and that dikes of other kinds of rock would have served the purpose equally well, for in many instances the granite or andesite breccia is ore-bearing along the course of a dike and in contact with it, while the dike itself contains no mineral of value, this being particularly noticeable in the basalt. This simply indicates that the dikes have merely afforded a deep-seated channel or fissure for the passage of mineral-bearing solutions and that these solutions deposited their contents under favorable conditions in those rocks best suited, both physically and mineralogically, to receive them, and generally the dense basic rocks appeared to have been less susceptible to the attack of these percolating solutions than the granite and the breccia. It is true that veins and ore deposits occur in dikes and large eruptive formations in many regions, but it has never been conclusively shown that the values in these veins and deposits were derived from the dike rocks themselves. It must then be assumed that they came from a deep-seated source—probably as deep as that from which the dike itself came, the solutions following along the plane of the fissure formed by the intrusion of the dike. Ore deposits commonly occur at contact of a dike with an older rock, and not infrequently the dike is sheeted by the intense pressure and movement which takes place along the plane of the fissure occupied by the dike—a natural line or plane of weakness. In some such instances ore deposition has taken place in this zone of crushing and shearing within the dike itself. Conditions of this character are not of infrequent occurrence in diorite, quartz-porphyry and other rocks.

The mineralization of this sort is not confined to any particular class of rocks, but basalt seems less suited to the reception of minerals from the solutions containing them than any other rock. It is a fact, long since recognized, that eruptive dikes and masses appear to have a direct influence on the deposition of ore in the rocks they penetrate. This influence of igneous rock on ore deposition is found to operate under a great variety of conditions and to be confined to no particular kind or rock or geological age. Ore is found associated with intrusive rocks in the Archaean schists and from that upward into the Tertiary formations. The intrusive rock may occur as a dike conformable with the enclosing strata, or it may cut across them. It is also often noticed occurring as flat, laccolithic sheets, as at Leadville, Colo., and elsewhere. There are few ore deposits of value which are not connected more or less directly with bodies of igneous rock, but it is not apparent that these igneous masses were the original source of the minerals found in the ore deposits, but rather that their intrusion, as previously suggested, merely opened a fissure or passage way for the ascending currents of mineral-bearing waters which deposited their contents in those places most available for such deposition. The minerals are deposited partly as a filling of interstitial spaces in the rocks, but usually more extensively as a replacement of one or more of the original constituents of the rocks. There are many regions where igneous rocks have been intruded, but where ore deposition seems to have been of limited extent or not having occurred at all, but these places are not common. In well-recognized regions of extensive mineralization, the ore deposition seems to have been more or less erratic, and in some places is lacking entirely, as viewed from a commercial standpoint, though all conditions, physical and mineralogical, are apparently favorable to the formation of ore bodies.

On the outskirts of such districts the mineralization grows less and less pronounced, though small bodies of high-grade ore are of frequent occurrence. The natural laws influencing ore deposition are not as yet well understood. A few facts—the most pronounced conditions—have been noted, and upon these has been built a structure or theory by means of which it is attempted to prove the source and causes of ore deposition, but sufficient has not yet been learned to make the knowledge positive and far reaching. The one who has the best opportunity to

observe the result of nature's forces and apparent vagaries is the miner who, foot by foot, works his way into rocks following his vein by shaft, drift and winze, or stope. He sees the frequent changes—valuable evidence—but he destroys this evidence as fast as he uncovers it. He is not trained usually to view these occurrences from any other than a practical standpoint, and their scientific value in tracing out the processes of nature do not usually appeal to him. If he finds his vein with a clean "let go" in one portion of the mine, but frozen to the walls in another, he merely considers the latter condition as a misfortune which will require more powder to break the ground and additional labor in caring for the ore. He does not seek for a geological, physical or a chemical reason for the change, nor give a thought to the causes which probably produced it. Undoubtedly if trained observers had this daily opportunity, more would be learned of the natural forces and conditions under which ore deposition has occurred. A great deal has already been learned in this direction and the knowledge thus gained is of incalculable value in the business of mining, but without doubt, the next succeeding years will see further advancement in our knowledge of this important subject.

WITHIN the week five more American mining engineers and miners have been murdered by Yaqui Indians in the State of Sonora, Mexico, and that, too, after requesting an escort—which they were assured was unnecessary, as there was no danger. Mexico invites the capital and experience of the United States to assist in the development of the vast resources of that republic, and yet permits a condition to exist which makes it possible for Americans, who are in the peaceful pursuit of their legitimate business, to be shot to death by a few score of Indian desperadoes. It is the candid opinion of every well-informed American in Mexico, and of those who live near the international boundary on this side of the line and who are thus in a position to be well informed as to the facts, that the republic of Mexico could, if so disposed, within thirty days put an end to these constantly recurring massacres of innocent men, both Americans and Mexicans. One of the engineers killed, John K. Mackenzie, had just arrived from Chicago to examine a mine in the mountains back of Hermosillo, and, although it was commonly stated that the Yaquis were on the warpath, the officer in charge of troops at Hermosillo declared that there was no danger. There are still a great many mining engineers and miners in the mining districts of Sonora at this time, and their friends have grave fears for their safety. What steps the Mexican Government will take toward rendering life and property safe in Sonora remains to be seen. The Indians have been raiding that section for several months past, but the efforts on the part of the Government to put an end to it show little of a determination to handle the situation as vigorously as the existing condition appears to warrant.

WITHIN the past three months three separate instances have been recorded wherein coal consumed in firing steam boilers is reported to produce an ash containing gold. One of these is near Florence, Fremont county, Colo., one in Wyoming and the third from the coal mines near Lemhi, Idaho. In the latter instance it is said the ash contains \$2 per ton. In the Crested Butte district of Colorado the coal measures and the coal veins themselves are intruded by igneous dikes and there are many of the geological features present commonly observed in regions of extensive ore deposition, but no gold has as yet been reported in the coal from that district if it occurs. Instances are also reported where the coal is said to contain copper sulphide. The appearance of iron sulphide in coal is of common occurrence—too common in some coals—but although copper is not actually generally known to exist in coal, there seems no good reason why a copper sulphide might not be precipitated in coal as readily as iron sulphide or gold either for that matter. Carbon is a recognized precipitant of minerals from their solutions and if waters carrying gold, silver, copper, iron and other mineral matter in solution penetrates a bed of coal, there seems no good reason why precipitation should not take place in the coal vein as readily as in sandstone shale, igneous or other rock.

## CONCENTRATES.

GASKETS for steam pipe joints may be made from sheet lead, which are superior to those made from rubber or leather.

THE Western Federation of Miners was organized in Montana in 1878, and has since extended to every mining State of the West.

THE first electric mine installation in California was the plant put in near Kelsey, El Dorado county, to run the machinery of the Dalmatia mine. It was destroyed by fire in 1899.

A COPPER HAMMER is a convenient tool about machinery, as a key may be driven as well with a copper hammer as with one of steel, and the former makes no marks on the key.

SOME MILL BUILDERS prefer to build mortar blocks and lower them into the pits, others build them in the excavations prepared for them. There seems little choice in the matter.

THE amount of tungsten annually consumed in Great Britain is stated to be about 1000 tons annually, but this is likely to be increased if the price of the ore is not increased to a prohibitive point.

IN 1895 the United States produced less than one-third of all the aluminum in the world. In 1903 the United States produced nearly one-half of all the aluminum manufactured in the world, the amount being 37,422 tons.

WHERE in a placer the gold follows a narrow pay-streak, and the depth to bedrock is 10 to 12 feet, it may be worked by sinking a series of pits 5 to 10 feet apart, connecting the pits and bedrock by tunneling—the species of mining known as coyoteling.

COPPER ORE in which the sulphide ore (chalcopryite) is associated with iron carbonate could probably be successfully concentrated by roasting sufficiently to render the siderite magnetic and then running the pulverized mineral through an electro-magnetic separator.

THE proper grade for canvas tables concentrating slimes after machines should be determined by experiment. A fall of 1½ inch to the foot gives good results in some instances. Canvas tables should be arranged so that the grade may be changed whenever desirable.

MINE timbers are framed so that adjacent members of the same set or system fit snugly, but no timbers in a mine are joined—that is, provided with tennon and mortise. In the square set the mortise and tennon are merely incidental—a portion of the system—the mortise being formed by the union of four timbers.

PORPHYRY is a term used to indicate a structural condition in a rock. Any rock in which crystals larger than the average of those composing the mass occur is called porphyry. Thus quartz-porphyry, granite-porphyry—a normal granite in which occur large feldspar crystals—hornblende-porphyry, etc., are examples.

NO MINE PUMPS are made which are not damaged by grit and coarse dirt, but some are so constructed as to be superior to others under such conditions. It is less expensive to send up the coarse, sandy dirt in the bucket than to pump it out. The raising of so much grit can be partly overcome by placing a finer screen around the lower end of the suction.

PLATINUM is somewhat heavier than gold. A cubic foot of the former weighs about 1312 pounds. It varies slightly, the specific gravity being 21 to 22. The specific gravity of gold is also variable—according to Dana, 15.6 to 19.3, and 19.33 when pure. All gold, until artificially refined, contains some silver. The specific gravity of silver varies from 10.1 to 10.5.

A SHAFT of two or more compartments, in which ventilation is poor, may have the condition improved by constructing an air-tight partition between two of the compartments. This may be still further improved by the construction of a tower above one of the compartments, which makes one side of the shaft deeper than the other and a current of air is thus induced.

THE only way to get rid of partners in a mining claim who fail to do their share of annual assessment work, or who refuse to pay for their share of the work, is by the means prescribed by law—"advertising them out." One partner may do the work, and then upon failure of the others to contribute their share in cash the proceedings to dispossess them may be commenced.

NATURAL BLUESTONE, or blue vitriol, is known as chalcantith—a natural copper sulphate. It is often seen as an efflorescence on old copper dumps and ore heaps that have been roasted. It is blue to greenish blue, sol-

uble. The taste is metallic and nauseating. It is often in solution in the waters issuing from copper mines. It occurs in large quantities at some mines, notably in Arizona.

IF sufficient water under pressure is not available to lift the gravel from the pit by means of the hydraulic elevator the next best means of raising the gravel to the sluice boxes on the rim of the pit would be by means of a ropeway and bucket or skip operated over the pit. This method is sometimes employed to stack tailings on level ground where they must be removed as they come from the mill.

WHERE the owner of a hydraulic placer mine has failed to perform the required assessment work, and the property is located by another under the law permitting such relocation by reason of forfeiture, any improvements, such as pipe, giants, etc., become the property of the relocater, for the reason that the former owner has no longer a right on the property and may not enter to remove his pipe, etc., being in the eyes of the law a trespasser.

IN the Eastern States coal is found in the rocks of the older formations—Carboniferous, etc. Coming westward, the coal measures are found at higher geological horizons. In the eastern Rocky mountain section the coal occurs in the Cretaceous. On the Pacific coast it is mostly in the Tertiary. In Riverside county, Cal., a coal vein 10 feet and more in thickness is found in Tertiary sandstone not more than 40 feet above crystalline schists and granite.

THE practice of sweating and chiseling mill plates to secure the last available bit of gold deposited on them is a bad practice, as it not only entails additional work, but injures the plates, particularly the chiseling, and moreover the plate requires much more attention, time and labor in dressing and securing a new surface of gold amalgam on the next run, necessitating frequent stoppages of the mill. It is doubtful if anything is really gained in the end by the practice.

THE right of a junior locator to follow his vein in depth beyond the side lines of his location and beneath an agricultural patent has never been positively determined by the Supreme Court of the United States, but Judge Sawyer decided in the case of the Amador-Medana G. M. Co. vs South Spring Hill M. Co. that the mine owner could not take his extralateral right under such circumstances. Before the case reached the Supreme Court, the matter was settled out of court, which leaves the question still open, as far as the highest court is concerned.

THE locator of a mining claim does not lose his right to a claim for failure to perform the assessment work required by law so long as no one relocates the claim, but should a relocation be made by another, because of such failure, the original locator has no recourse. The prior locator may neglect to perform the assessment work for several years and still retain possession so long as he is not disturbed by the entry of another for the purpose of relocation. So long as the first locator remains undisturbed he may resume work at any time and his title will still be good as between himself and the Government.

THERE are numerous instances where steam pumps in mines have been submerged, and which responded when the steam was turned in and promptly began to work. When water rises in a mine and the pumps have to be abandoned, it is a wise plan to open the pet cocks on the steam cylinder. If the weight of the column of water on the piston is not greater than the steam pressure, the pump should start and run smoothly. At a mine in Tuolumne county, Cal., a pump was started in this manner which was submerged under 100 feet of water, and the mine was drained by the pump without trouble.

THE iron ores of the Lake Superior region are handled by means of special cranes, travelers and other mechanical apparatus. It is seldom that these methods are applied to the handling of other metalliferous ores, probably for the reason that usually they are treated in works near the place of their production, while in the case of the iron ores they are shipped often long distances by rail, unloaded into great piles and reloaded into ships, from which they are again moved onto wharves and sent by rail to the smelters. In every instance the ore is taken to the fuel, though less fuel than ore is employed in their reduction.

ONE of the earliest mining camps of California is said to have been the Cargo Muchacho mountains, in San Diego county, about 20 miles from Yuma. At one place it is reported several thousand dollars in nuggets were picked up on the surface. Something similar was found on Rich hill, a few miles north of Wickenburg, Ariz. Near the latter locality nuggets of born silver were found in the wash of an arroyo. Masses of horn silver in placers are of rare occurrence, and could only exist in a country of very slight rainfall, as, owing to the soft nature of the mineral, nuggets would quickly be destroyed by the abrasion of the rocks in a flowing stream.

THE number of cubic feet of ore required to make one ton in place is usually estimated at 13 cubic feet. This

varies somewhat with the character of the ore. A porous "honey-combed" ore, from which sulphides and other minerals have been leached, will require more than 13 cubic feet—sometimes as much as 20 feet or even more—while a heavily sulphureted ore, or one in which occurs a large amount of baryta (heavy spar), or the manganese minerals, rhodonite or rhodochrosite, will require less in proportion to the amount of the minerals of high specific gravity present. It is difficult to estimate the value in precious metals in ores by their "heft," as determined by holding in the hand.

IT is stated that the noted Brooklyn bridge built over the East river, and connecting the cities of New York and Brooklyn, must be rebuilt. The bridge was commenced about 1871, and completed in 1879-80 at a cost of \$15,000,000. It has therefore been in constant service for about twenty-five years. At the time of its construction it was looked upon as one of the most noted works of modern engineering, but has cost nearly \$5,000,000 to keep the great structure in a condition of safety. It is partly due to overloading that this magnificent structure has so rapidly deteriorated, but the most important factor in its destruction is said by competent engineers to be electrolysis. It would seem that some means of obviating this disastrous result may have been applied.

THERE is much diversity of opinion as to the most desirable place for the main shaft of stamp mills. In many instances the shaft is placed on the cam floor in front of the batteries, the belts running horizontally to cam-shaft pulleys. This is done on the front-knee frame type of mill. In other cases the shaft is generally placed back of the mortar either on or beneath the feeder floor. In most mills where the latter is adopted, there is a lack of light and ready accessibility, but this may be remedied by carrying the shaft on a line of concrete foundations raised about 30 inches above the floor. This renders the lining up of the shaft convenient and all repairs, babbitting, etc., can easily be attended to. There are other situations for line shafts, but they possess few, if any, advantages over those above mentioned.

COPPER ORES often occur in flat sedimentary formations in both sandstone and limestone—in sandstone in Paradox district, La Sal mountains, on the border of Colorado and Utah, and in limestone at St. Genevieve in Missouri. These are only two illustrative instances. The conditions mentioned in Mississippi are not an impossible environment for the occurrence of copper ore. It is very doubtful if the assay on the ore mentioned is reliable, as neither chalcopryite nor any other sulphide of copper contains 90% copper. The richest copper ore is cuprite, the red oxide, which contains 88.8% copper. The presence of gold and silver in copper ore is not of unusual occurrence. It is unlikely that the mineralization would extend downward into the underlying strata under the conditions described, although it is not improbable that lower strata may be found mineral bearing, as this is not infrequently the case and such does occur in both of the instances above referred to in Colorado and Missouri.

THE amount of gravel that may be moved daily by hydraulicking is exceedingly variable. There is no constant relation between the quantity of water employed and the amount of gravel moved, even under the same head, with a given amount of water. With given conditions as to the gravel, the amount that may be moved is determined by the quantity of water and pressure available. If either the quantity of water or the head be increased, the volume of gravel that may be moved increases, but the gravel varies greatly as to size of material composing it, and also as to its nature. The gravel banks present every variety of condition from that which is free and readily washed through various stages of cementation to that which is thoroughly compacted and requires blasting to disintegrate it. A stage beyond this and the gravel becomes conglomerate and must be crushed in a mill. Under more ordinary conditions, such as usually obtain in hydraulic mines, the quantity of gravel that may be moved with a miner's inch of water ranges from one to twenty-four cubic yards per twenty-four hours.

A SMALL DRILL BIT will cut more rapidly than one of large cross section, consequently it costs less to drill a given depth of small hole than the same depth of large hole, and this applies to either hand or machine drilling, regardless of the kind of machine. In some ground it is advisable to use a wider bit, as a small hole will not admit of the introduction of sufficient powder to break the hole satisfactorily. If a hole be loaded too near to the collar it is likely that the upper end of the hole will break while the bottom of the hole remains intact, necessitating the reshooting of the hole, particularly if it be a deep one. In deep holes in hard rock it is advisable to employ high-grade powder—70% nitroglycerine—as this is more likely to cause the ground to break than a lower grade of powder. It is never good judgment to overburden a hole. It is better to drill the holes to a lesser depth and to have them break than to be obliged to repeatedly shoot them until the ground is broken. There are certain principles which underlie successful blasting which experienced miners well understand, particularly those who have gained their knowledge by the use of the hand drill, and these principles all miners should endeavor to learn and apply.

## The Use of Mercuric Chloride in Testing Cyanide Solutions.

Written for the MINING AND SCIENTIFIC PRESS by  
LEONARD M. GREEN.

During the investigation of the constituents of some working cyanide solutions containing copper, the author had occasion to study the reactions of mercuric chloride on copper double cyanides and, incidentally, on zinc double cyanides.

Hannay's mercuric-chloride-ammonia test for cyanide solutions is seldom used on account of the interference of impurities, such as zinc, ferrocyanides, etc.

As is well known, when a pure cyanide solution is titrated with mercuric chloride, potassium chloride and mercuric cyanide are formed.

When the whole of the cyanide has been converted into mercuric cyanide, if the titration is continued, free mercuric chloride is left in solution, and if a suitable indicator is present to show the presence of mercuric chloride in excess, the quantity of cyanide present may be readily determined. Hannay uses ammonia, which forms a white cloud with the mercuric chloride.

In pure solutions this indicator is quite satisfactory, but in impure working solutions it is practically valueless.

An indicator, however, which gives exceedingly good results and a sharp end point is potassium-mercuric iodide, made by adding mercuric chloride to a solution of potassium iodide, till a permanent pink coloration is just produced.

If a pure cyanide solution, to which has been added some mercuric potassium iodide, be titrated with mercuric chloride, when the whole of the cyanide has been converted into mercuric cyanide, the next drop of mercuric chloride solution causes a scarlet precipitate of mercuric iodide. The reaction is exceedingly sharp.

The precipitate is somewhat soluble in and its color is affected by caustic alkalies, but it is not affected by alkaline carbonates or bicarbonates. Consequently, if to a cyanide solution containing alkaline hydrates an excess of sodium bicarbonate be added, together with some potassium mercuric iodide as indicator, the cyanide may be successfully titrated with mercuric chloride.

If zinc-potassium cyanide is also present, the whole of the cyanide in the zinc double cyanide is estimated; but when copper double cyanides are present, only a portion of the cyanide combined with the copper is indicated. If, however, an excess of potassium ferrocyanide be added, the whole of the cyanide combined with the copper is also determined.

The cyanide combined with copper and with metals forming double cyanides similar to copper double cyanides, although not indicated by the ordinary silver nitrate test, may therefore be determined by the following method:

### DETERMINATION OF CYANIDE IN COMBINATION WITH COPPER.

**STANDARD SOLUTIONS.**—Silver Nitrate: Dissolve 13.05 gms. of pure crystallized nitrate of silver in distilled water and make up to 1 litre.

1 c.c. of this solution = 0.01 gm. KCy.

**Mercuric Chloride:** Dissolve 10.422 gms. of pure mercuric chloride in distilled water and make up to 1 litre.

1 c.c. of this solution = 0.005 gm. KCy.

**Potassium Mercuric Iodide Indicator:** Dissolve 1 gm. of potassium iodide in distilled water; add mercuric chloride solution till a permanent pink tinge is produced; then add 2 gms. of potassium ferrocyanide and 2 gms. of sodium bicarbonate and make up to 200 c.c.

Use 10 c.c. of indicator for each 10 c.c. of cyanide solution tested.

**TESTS.**—I. Take 10 c.c. of solution to be tested; add a slight excess of caustic soda solution and a little potassium ferro cyanide, together with a few drops of a strong solution of potassium iodide. (If ferro-cyanide is not added the result is apt to be slightly high where much copper is present.) Titrate with silver nitrate solution till a permanent yellowish cloudiness is formed. Disregard any slight whitish cloudiness sometimes occurring previously.

Result = 'a' c.c.

II. Take 10 c.c. of solution; add 10 c.c. of potassium mercuric iodide indicator; titrate with mercuric chloride solution till a permanent reddish coloration is formed; disregard any purplish coloration sometimes occurring previously, which is due to the precipitation of copper ferro-cyanide.

Result = 'b' c.c.

Then the cyanide combined with copper

$$= \left( \frac{b}{2} - a \right) \% \text{ (considered as KCy).}$$

N. B.—When silver is present in any quantity, it causes the color at the end point to be a yellowish-red to orange, instead of red.

In solutions containing zinc, another curious reaction occurs which may sometimes be found useful.

If a solution of potassium cyanide and potassium zinc cyanide, to which is added a large excess of potassium ferro-cyanide and sodium bicarbonate, be titrated with mercuric chloride solution, when two-thirds of the potassium cyanide has been taken up by the mercuric chloride (viz., when the  $\text{HgCy}_2$  and  $\text{KCy}$  are in the proportion of  $\text{HgCy}_2$   $\text{KCy}$ ), the further addition of mercuric chloride causes a white cloud of a ferro-cyanide precipitate, which the author believes to be a double ferro-cyanide of mercury and zinc. This precipitate is soluble in potassium cyanide, but is not soluble in  $\text{HgCy}_2$ ,  $\text{KCy}$ , nor in alkaline carbonates and bicarbonates.

This reaction suggests a method of determining zinc, which the author believes may sometimes be useful where a rapid determination is required.

**DETERMINATION OF ZINC.**—III. Take 10 c.c. solution; add a large excess of potassium ferro-cyanide and of sodium bicarbonate; dilution barely affects the result; then titrate with mercuric chloride solution until there is a permanent milky cloud formed; towards the finish add the mercuric chloride 2 drops at a time, waiting about twenty seconds between each addition.

Result = 'c' c.c.

This result represents two-thirds of the potassium cyanide present. Therefore, the potassium cyanide equals  $\frac{2}{3}c\%$ .

By Test I the potassium cyanide + the potassium zinc cyanide =  $a\%$ .

Therefore, the potassium zinc cyanide =  $(a - \frac{2}{3}c) \%$  and the zinc =  $\left( \frac{4a - 3c}{16} \right) \%$ .

The reactions given in this paper are only some of the more interesting reactions of mercuric chloride with cyanide solutions, and the author believes that this solution might often be used with advantage in place of or in conjunction with silver nitrate solution.

City of Mexico, Jan. 18.

## A Continuous Slime Filter.

Written for the MINING AND SCIENTIFIC PRESS by  
ALGERNON DEL MAR.

The vacuum slime filter herewith sketched is an outline for a continuous filter, one that is continuous in operation, and, although not actually tried, the inventor believes he sees his way to overcome the mechanical difficulties. This filter, worked in conjunction with the steam agitator illustrated some months ago, should make an ideal process.

Proposed Continuous Filter.

The filter wheel A C is made in one casting an inch thick, planed on both sides, divided into eight or more compartments, containing filtering space of 1 square foot on each side, or a total of 16 square feet of filtering surface in the one unit. The filtering spaces are covered with the filter cloth and thin sheet of perforated steel over this, so that the compartments outside will be even (plane) enough to use a scraper and spray to remove the accumulated sludge. Each compartment, A A, has a valve, B B, opening into the chamber, F, with a spring that can be tightened to any required tension. The hollow cylinder, C, the axis of the wheel, is connected with a vacuum pump which exhausts the air from F and through the valves B from the compartments A. This filter wheel revolves at any desired speed in the annular grooved receptacle E, the groove D being kept full of slime. As the wheel revolves the receptacles A A dip beneath the slimes. The vacuum then begins to act, the liquid filtering through the cloth and the solid matter clinging to the surface. When any one compartment has traversed the space from D to D' the economical limit of filtering is over, and as the compartment rises out of the slime the sludge is automatically scraped off and washed with a jet of water under pressure. As soon as a certain amount of sludge is swept off the air enters A, and unless the valve is automatically shut the vacuum in the other compartments would suffer. The sheet iron or steel that completely covers the space F has eight small stuffing boxes, through which project eight rods, one for each valve, so that

as soon as the compartment revolves out of the slime the rods are automatically pushed in, completely closing the valves, keeping them closed until they dip under the slime again.

A modification of the idea above outlined would be to have the vacuum boxes on the periphery of the wheel instead of on the side, or they might be on both.

## Gypsum and Its Manufacture.

Gypsum is a hydrous calcium sulphate. It is a compound of calcium and sulphuric acid combined holding water of crystallization. The percentage of these components by weight is calcium 32.5, sulphuric acid 46.6, water 20.9. The principal varieties are selenite, a transparent kind occurring in plates and sheets, often of considerable size; satin spar, a fibrous variety with silky luster; alabaster, a compact, dense variety, and an earthy dull variety often containing impurities. It is often associated with rock salt, due to the fact that both salt and gypsum are residual deposits left by the evaporation of sea water; the salt, being precipitated more readily, is generally found beneath the gypsum layers.

Gypsum occurs in seventeen of the United States, and is abundant in the localities of its occurrence. It is used in the manufacture of plaster of paris and as land plaster. In the process of manufacture of plaster of paris the gypsum is calcined, in the process of which, when sufficient heat is applied, the water of crystallization escapes as steam, the crystals are disintegrated, and the mass boils vigorously. When the temperature reaches about 132° C. the boiling ceases and the material settles down in the kettles, and it may then be seen that the material has decreased in volume by loss of water. When the temperature lowers to 177° C. the mass is removed from the kettles, the temperature being checked before all the water is driven from it. The process of manufacture varies in the different works in the United States, though the methods are about the same. The difference lies chiefly in the character of material treated. The earthy gypsum requires less machinery than the gypsum rocks, as the latter requires crushing machinery which may be dispensed with in treating the former; the earthy gypsum is also generally less expensive to mine. It is taken from the beds by whatever means seems best applicable. In some instances it may be shoveled or scraped up into wagons. In others it must be plowed up or loosened. Rock gypsum often requires blasting. The impure kinds or portions are used for land plaster. The rock material is delivered in lumps at the mill when it is passed through crushers. It is next ground into coarse grains between buhrs, or rolls similar to those used in flour mills. Other types of machinery are sometimes employed for accomplishing these results. From the granulating machines the gypsum is conveyed to the calcining kettles, which are cylindrical in form and placed vertically in brick work. The heat is applied beneath, and usually passes upward through pipes or flues which are arranged within the kettle. In the process of cooking the gypsum is added gradually, the mass being stirred by revolving arms, which prevents the material on the bottom from burning and also aids in an even distribution of heat. When the gypsum begins to cook, the water which is driven off causes it to boil vigorously. The boiling ceases at a temperature of 132° C. The mass settles in the kettle as a result of the loss of water. As a higher temperature is reached boiling recommences, but is much less vigorous than before. At 177° C. the valve at the bottom of the kettle is opened and the mass of pulp is drawn off, and is cooled on a floor or in a bin. The temperature is noted during boiling by means of a thermometer, but the operator soon becomes expert enough to judge the degree of heat by the appearance of the boiling gypsum. The boiling must not be carried so far as to expel all the water, for if this occurs the plaster will not set readily. Good plaster of paris depends upon the presence of a small amount of anhydrite, around which crystallization begins and is continued until the entire mass is "set." After cooking and cooling the gypsum is passed through fine screens, and is sometimes even reground before sacking. The oversize from the screens is usually mixed with fresh material and recalcined. There are a few plants employing rotary-cylinder furnaces similar to those used in making clinker for Portland cement, but these are of special construction. Superheated steam has also been experimentally used in cooking gypsum, but this, evidently the coming process, has not as yet been perfected in all its details. Although gypsum occurs in scores of places throughout the West, one of the most interesting occurrences is that in western South Dakota and eastern Wyoming, about the Black Hills uplift, where it is found in beds often over 40 feet in thickness, and of dazzling whiteness, resting upon the bright red shales and marls of the Triassic. Where erosion has not removed the Jurassic rocks the gypsum is overlaid by buff and greenish colored sandstones. This combination of colored rocks and the green foliage of trees and grass gives a picturesqueness to the scenery rarely found elsewhere. The valley in which the gypsum beds occur com-

pletely encircles the hills, and the deposit is almost continuous for over 300 miles. There are several plants in the Hills, for the manufacture of plaster of paris, land plaster, etc. These are at Sturgis, Spearfish and Hot Springs. Commercial success in the manufacture of the raw material is largely dependent upon cheap transportation, which is not always available in the districts where gypsum is most abundant.

### A Redwood Forest.

Although nearly all of the forest trees of the West are used in mining, including most of the conifers, the redwoods, which grow so abundantly and of such magnificent size in California, are used to only a limited extent in mine timbering. In the New Almaden quicksilver mines in Santa Clara county, Cal., redwood was used extensively for mine timbers for many years, but lately their use has been discontinued for Oregon pine and other pine timbers. The accompanying illustration is characteristic of a California

required to furnish forth a summer lounging place or a dining room for the adjacent habitation. These facts argue the difficulty of clearing farms in the redwood region, but of that we shall speak more in detail upon a later occasion.

These redwoods should not be confused with the *Sequoia gigantea*, or "Big trees" of California, although the former are also of the same genus—*Sequoia semper virens*. These two species are the only kinds known. The *semper virens* is found in the Coast Range only, and the *Sequoia gigantea* in the Sierra only, occurring in a series of isolated groves from Calaveras county on the north to Tulare county on the south. These mammoth trees are only equaled in their great height by some varieties of the eucalyptus of Australia.

### Strength of Timber Treated With Preservatives.

With the increasing use of timber, preserved in one way or another against decay and fire, it is important to determine the effect which the preserving

processes have upon the strength of the preserved timber.

This general plan was pursued at the timber-treating and testing station at St. Louis in accordance with the following outline:

(1) To determine the effect of the preliminary processes, such as steaming, on the mechanical properties of the timber.

(2) To determine the effect of the preservatives on the strength of timber, eliminating the effect of the preliminary processes.

In order to determine the effect of these factors, the programme was divided into two parts—part 1, the effect of the preliminary process, and part 2, the effect of preservatives.

The effects of the preliminary process were determined only on loblolly pine—a variety common in the Atlantic and Southern States. Both green and seasoned timber was used in determining the effect of preservatives. The preservative fluids investigated included only creosote and zinc chloride.

In making comparative strength tests of treated and untreated timbers it is necessary to eliminate, as far as possible, the variations due to the great differences in quality of individual pieces of wood.

View in Bohemia Grove of Redwoods, Near Guerneville, Sonoma County, Cal.

redwood forest, this view being of the Bohemia Grove, near Guerneville, Sonoma county, and is reproduced from an excellent photograph taken by Mrs. W. A. Turner of Guerneville. One of the peculiar features of the redwood forest is its practical indestructibility by fire.

Though fires may rage through the undergrowth, the trees are not destroyed, though the lower bark may be often sadly disfigured by surface burning. But this indestructibility of the redwood and its resistance to decay makes the clearing of redwood lands difficult and expensive, while at the same time it renders the forest self-perpetuating, in spite of even wasteful lumbering. Second growth of redwood from the stump is clearly seen to be of immense age. More recent second growths show how the older instances came about. The primeval trees were of enormous size and the growth from suckers around their rooting, therefore, described a circle of great diameter. The succession of grand trees around a common center forms an enclosure of considerable area, and many such an area serves as a retired recreation retreat or as an auditorium for forest oratory, or sermonizing, or dancing, as the tastes of the visitors may incline. As there are very large circular enclosures, so there are smaller ones, marking the sites of smaller central stumps, and the second growth is so rapid that not many years are

process has upon the strength of the preserved timber. Many engineers believe that creosoted timber is more brittle and less capable of withstanding strains than the same timber before being treated with creosote. This is particularly true with bridge timbers and piling.

Actual tests are necessary to determine what relationship exists between the preservative process and the strength of the timber. Most of the tests hitherto made with preserved timber were made by comparing results of tests on treated sticks with results on untreated sticks. In many instances these turned out in favor of the untreated timber. The reason why such tests are unfair to the preservative is that in the process of preservation two factors enter: (1) The actual process of impregnation with a preserving substance, and (2) the preliminary processes of steam seasoning, in the majority of treating plants in the United States. A piece of timber subsequently treated with creosote may be steamed to such an extent that the timber becomes exceedingly brittle. This, obviously, will be the fault of the steaming and not of the creosote.

Timber preservation divides itself broadly into three stages: First, the preliminary preparation; second, the actual preservative process; and third, the treatment of timber following preservation. The final strength of the timber may be influenced mate-

This was accomplished in this case by using 11-foot timbers cut at the same time from one forest site. In testing the influence of preliminary processes of seasoning, a 3-foot section was cut from one end of each timber and sawed up into test pieces, which furnished a basis of comparison between (1) the results of tests of these "control" pieces, and (2) the results on test pieces taken from the remaining 8-foot section after the latter had been subjected to the various preliminary seasoning processes in the treating cylinder.

In testing the effect of preservatives themselves, the entire 11-foot timber was subjected to the preliminary seasoning processes, after which a 3-foot section was cut from the end of each timber. The 3-foot section, thus having been subjected to the preliminary seasoning processes, formed a basis of comparison with the remaining 8-foot section, which was treated with the preservatives. In this way the separate effects of the preliminary processes and the effects of the preservatives could be isolated and determined.

Because of an apprehension that defects of brittleness of treated timbers might not be evidenced by the ordinary tests under slowly applied loads, provision was made for both static tests and impact tests. The test pieces were subjected to cross bending strain, compression along the grain under both static and impact conditions, and under shearing

parallel to the grain and compression at right angles to the grain under static conditions. The data taken include the moisture conditions, specific gravity, and rate of growth. During the treating operations, records were kept of the temperature to which the timbers were subjected at all stages, the amount of preservatives absorbed, as indicated by gross weight and subsequent chemical analyses of the test pieces.

Ordinarily, the strength tests were made immediately after treatment in the cylinder. In order, however, to determine what weakness might be introduced by changes in the physical conditions of the preservatives in the wood through lapse of time, a complete series has been set aside for subsequent operations. An additional set of test pieces has been loaded with different percentages of the strength, as exhibited under the ordinary tests, and this load allowed to act for long periods of time, the deflections being measured from day to day.

While this programme is not sufficiently advanced to allow the drawing of final conclusions, yet the preliminary results are fairly indicative of what may be expected. It is found that the steaming process weakens the resistance of the wood fiber to both static and impact loadings. It may be stated that this diminution of strength is very nearly in direct proportion to the length of time that any given steam pressure is applied. The diminution of strength was found to be 25% after a pressure of twenty pounds was applied for ten hours to green loblolly pine, and 10% when a pressure of twenty pounds was applied for four hours. This diminution of strength increased very rapidly when the pressure rose above twenty pounds, and amounted to about 25% when a pressure of fifty pounds was applied for four hours.

It will be easily seen that when the conditions of time and pressure are made very severe, the conditions prevailing in the pulp mill industry will be approximated. Evidently, it is well to avoid when possible the use of these preliminary steaming operations in the wood preserving industry.

With relation to the effect of preservatives themselves, the latter is distinct from the preliminary process. It may be said that the treatment with zinc chloride does not seem to further reduce the strength of timber beyond the effect of the steaming process. This might have been expected when it is considered that the strength of the zinc chloride solution ordinarily used does not exceed 2½%. The strength of timber that had been treated with the 2½% solution of zinc chloride, after having been steamed four hours at twenty pounds pressure, was the same as that of timber which had been steamed without the subsequent application of zinc chloride. The same statement may be made of timber treated with an 8½% solution of zinc chloride. It may be that subsequently the crystallization of the zinc chloride will weaken the wood fiber. This remains to be determined.

The effect of the creosote appears to be the same as that of an equal amount of water in weakening the fiber. That is to say, the strength of creosoted timber is that of green timber. The difference is that while green timber gains strength upon seasoning, the creosote oil remains in the wood, and, it appears from analysis of a pile thirty-five years old, that the oil remains in a liquid condition. Consequently, comparison between seasoned timber and creosoted timber will always result to the disadvantage of the latter, as far as its strength is concerned. In the case of creosoted wood, it also remains to determine what changes in the wood fiber take place through lapse of time in the presence of creosote oil.

It is expected that a bulletin will be issued by the Bureau of Forestry upon the results of these investigations when the tests are completed. This bulletin will also contain the results of the investigations to determine the best methods of preserving wood, so that the maximum impregnation may be obtained with the least expenditure of oil per cubic foot of timber.

### Remedying Unsanitary Conditions of Mines.

Written for the MINING AND SCIENTIFIC PRESS by  
MATT. W. ALDERSON.

The Governor of Montana in his message to the Legislature now in session says:

"Information has just reached me through the inspector of mines that the sanitary condition of the Butte mines is very bad. Whatever is necessary to remedy this should be promptly supplied."

The Governor quotes extensively from the report of the inspector, who says:

"In the Butte mines conditions have become so bad in a sanitary way that a reference to the statistics of mortality in that city will show that at least 100% more men die from diseases caused by bad sanitary conditions in the mines than result from all mine disasters."

The report recites that in the city above ground excellent sanitary conditions exist, but that for the 5000 or 6000 men laboring underground, who from the nature of things cannot come to the surface to attend to Nature's demands, and who use abandoned drifts, crosscuts and such other places as are con-

venient, a condition exists which demands a remedy. He recommends a law to provide for sanitary regulations in mines.

I presume this matter has received some consideration from every person who has worked in a mine. Many consider it but a moment, accept the situation and go ahead. I know I have wondered many a time what would be best and have then done what was not best. One day, however, I happened to notice that droppings left on the surface near a shaft where work was being done had disappeared. I became interested and observed that the droppings of one day had invariably disappeared by the next. I continued my observations to ascertain what animal could be the scavenger, and was led to the conclusion that it was a mountain rat and that the rat came from among those making their home in this old shaft, in which work had been renewed. Later, when an abandoned level was used in a mine, I made repeated observations and noticed that the excrement always disappeared the first night and the only sign left was a few granular droppings of the mountain rat.

I had always looked upon the mountain rat as a nuisance and was ever ready to wreak revenge upon him for borrowing candles from me when opportunity offered. But instead of being an enemy I now found that he was a friend, ready to perform a service for me without money and without price which it would be almost impossible for me to get done otherwise. We have been friends from that day, and if he chews a candle end off for me during the night, or if he comes down near where I am working and helps himself to a drink from my pail of drilling water, as I have had him do many a time, he is very welcome.

Since the above experience I have never hesitated to let my men make use of any part of a mine accessible to the mountain rat, having implicit confidence that our faithful scavengers would do even better service for us than the fowls do for the beasts of the field. And I venture to assert that men working in a mine where mountain rats make their home may violate what would be considered the most essential of sanitary regulations with impunity.

The remedy for imperfect sanitary conditions is obvious. Make the mine so that mountain rats may exist in proportion to the number of men employed. They will do better service than any system of sewerage or any lot of patented contrivances that may be put in to take their place.

### The Power Drill Sharpener.

Written for the MINING AND SCIENTIFIC PRESS by T. H. PROSKE.

When the modern air drill first came into use the single bit was replaced by the cross bit, owing to its greater cutting capacity and its lesser liability to follow slips and seams in the rock, which often resulted in the loss of a hole on account of being crooked.

The cross bit was forged from the octagon or round bar at that time in general use. To make these cross bits it was necessary to upset the bar to about twice its normal size for a distance of from 6 to 8 inches at one end previous to forming the cross. This was done in order that in redressing the bits a long stock of cross was available to work on. After this stock had been worked down, the bar was again upset as at first. This process of upsetting, especially by hand, was very expensive, as it was very laborious. In some of the larger mines in Michigan a large bolt-upsetting machine was installed to do this upsetting, which materially reduced this expense. The general use of these machines was not possible on account of their enormous cost. To overcome this, the drill steel makers began rolling out cross-formed bars of steel, to be cut into the desired lengths and then welded onto octagon or round bars. While this welding was expensive, it was cheaper than upsetting the bar, as was at first done, and this type of drill is in general use in the Rocky mountain mining districts.

When drill sharpening machines first made their appearance, one of the conditions met was that no two mines used exactly the same shape of drill. The only way that I can account for this is that the Creator did not make any two blacksmiths alike, and therefore each smith had his own peculiar form of drill. This difference in ideas often resulted in more or less trouble in the mine by the mixing of drills made by different smiths, and to overcome this a very wide range of gauge was adopted; in some cases a starter drill would be 3½ inches wide, and then they would drop ¼ inch in gauge as the lengths would change, and often the bottom of a 6-foot or 8-foot hole would be more than 2 inches in diameter. Into this hole so much powder was rammed that, instead of merely breaking the rock, it was pulverized to a sand. One-half the charge would have accomplished the desired result.

By the use of a power drill sharpener the gauge of the drills can be reduced to a size that is consistent with what is really wanted, and at no time should the gauge of the drill vary more than ¼ inch. As these machines positively gauge all drills regardless of who runs them, it is possible to use smaller drills, and in this way put down from 25% to 40% more holes than with the same air consumption.

Practice has determined the fact that where 1½-

inch powder is to be used, the bottom of the hole need not exceed 1½ inches. If the rock is so tough that 40% powder will not break it, then it is cheaper to increase the strength of the powder than to increase the size of the hole.

As the hardness of rock varies in the different mining districts, so must the drill vary to conform to these conditions; no matter what the depth of the hole is to be, the bottom should not exceed 1½ inch diameter for 1½ inch powder; if the hole shall be from

Type of drill used in Rocky mountain mining districts. Cross-formed bar welded onto octagon bar; shank forged to small bushing.

Type of drill used in Michigan copper and iron mines. Long cross upset in bolt upsetting machine from octagon bar.

Type of drill as made with a Power Drill Sharpener. Cross upset 3 inches long from round bar; no forging down of shank, as chuck bushing is large enough to take the full size of bar, the most economical drill that can be made.

8 to 9 feet deep, and four lengths of drills will put it down, then the starter drill should be 1½ inch wide as made by the machine, the second drill should be 1½ inch wide, the third, 1½ inch wide, and the fourth, 1½ inch wide. These drills will usually cut ¼ inch larger than their gauge, but should the rock be so hard that eight lengths of drills are required to put down a 9-foot hole, then the starter should be 2½ inches wide, the rest to follow at a ¼ inch drop in gauge. In a number of tests made it has been found that machine sharpened drills lose their gauge about one-half as fast as hand sharpened drills, so the smaller the starter drill the less the drill has to cut, and the faster it will go into the rock. The reducing of the size of the drills can only be safely done where a machine is used for sharpening.

These are some of the economies already accomplished; there are more to follow, especially where the cross-formed bars are welded onto the octagon bars; by the use of the power drill sharpener this welding is not necessary; neither is it necessary that the octagon bar be upset from 6 to 8 inches for stock; it is only necessary that there should be enough cross to sustain the bit, and usually 3 inches is sufficient for any size drill. The modern drill sharpener will easily forge this amount of cross and bit on the end of a bar without any hand work whatever, and, after having once forged it, it will maintain it until the bar is used up.

In some mines it has been found advisable to increase the size of the bushing in the chuck of the rock drill to take the steel without the necessity of forging down the shanks. This lessens the number of broken shanks, and even when a shank does break, the drill can be put back into the chuck at once without having to forge it down. In this way by using a power drill sharpener it is possible for one man to sharpen from 200% to 300% more drills than he can sharpen by hand, and on account of their accuracy in gauge they can be made smaller, and in this way the capacity of the rock drills underground is increased from 25% to 50%, and by dispensing with the welding of drills and shanking them, the work on the drills themselves in the shop is reduced fully 50%. Machine sharpened drills will not stick, or cause rifled holes.

### A View of the Comstock Lode.\*

Unusual attention has been attracted to the Comstock Lode at Virginia City, Nev., by reason of the engineering problems being solved there in the unwatering of the south, or Gold Hill, end of the great

Overman Mine, Gold Hill, Nev.

lode. For five years the Comstock Pumping Association has been successfully lowering and controlling the water of the central group of mines, by means of

\* See illustrations on front page.

a hydraulic elevator operating in the Consolidated California & Virginia shaft. The success in handling the large volume of hot water encountered in these mines has recently determined those interested to undertake the unwatering of the Gold Hill section in either a similar manner or by means of electrically driven pumps. In addition to these mechanical problems, the geological possibilities of the lode in the way of the development of new bonanzas is again affording much food for speculation in consideration of the recent developments in the Con. Virginia and the adjoining Ophir mine. Some very good ore has recently been found on the 2300 level of the former, though its extent is wholly undetermined. In the Ophir, a rich vein is being developed, the principal cutting in it at present being a winze, which is said to be wholly surrounded by the new ore. Although there are a great many shafts on the Comstock, from 2000 to over 3000 feet deep, there has been comparatively little exploration below the 2000 level and this mostly along the foot wall, and what may yet be found by deeper exploration is wholly an unknown quantity. It is noteworthy that the new discoveries are well into the hanging country, farther than ore has ever previously been found. There is still abundance of low-grade, but payable, ore in the upper portions of some of the mines, and also a great deal known in depth which would also probably yield a profit, if existing conditions could be changed somewhat, so that mining could be carried on in a manner similar to that practiced elsewhere, and at no greater cost, except as it is influenced by the great heat of the lode, which is one of the most important factors in the cost of working. The accompanying illustrations are of some of the surface works of important mines of Virginia City and Gold Hill, and are published through the courtesy of the Reno Chamber of Commerce, being from its recently issued interesting book, "Greater Nevada."

### Firing Blasts by Electricity.

The use of electrical fuzes is rapidly superseding the old cap and fuse method of firing blasts. It is therefore desirable that the details of this kind of blasting should be more generally understood.

In order to economize explosives when firing a long line of holes, it was once necessary to drill a hole, fire it, then select the most advantageous point for the next hole to be drilled, and so on. The time lost by workmen in moving tools and retiring from the vicinity of the blast was enormous, especially when a shot happened to miss fire or did not explode promptly, necessitating a long wait before it was safe to approach the shot and examine it. Before the days of electrical fuzes a great many expedients were tried in order to overcome these troubles and to find some way to fire all the holes in a blast line at, as nearly as possible, the same time—for it was generally understood that a great deal more work could be done by a given quantity of explosive if all the shots could be fired at the same time than could be done if even a small fraction of a second should elapse between the explosions. These attempts at simultaneous firing were crude and, compared with modern methods, ineffective, and serve only to illustrate the need of a better method.

With electrical fuzes, however, it is easy to fire a line of 10 or 100 holes at exactly the same time—in fact, it is difficult to do it otherwise—and that this simultaneous explosion of a long line of shots will do the greatest possible execution needs no argument (Fig. 1). Furthermore, special methods of loading, which would be impossible with common fuse, are easily carried out by using electrical fuzes. The safety of the electrical method deserves equal consideration. With a blast to be fired by common fuse there is always the chance that a piece of fuse left burning in the hole after springing may set fire to the explosive and cause a premature explosion. The statistics of accidents which have occurred in the use of explosives show a great many cases of this sort. Then there is the old story of the blaster, who thought the fuse had gone out, and approached the blast to examine it about the time it exploded. With electrical fuzes accidents of this kind are eliminated. Not only does the blaster know just when the explosion is to take place, but he is able to retire the workmen to a safe distance with the least possible loss of time. If by reason of some improper connection a blast fails to explode, he can at once disconnect the blasting machine and set about an examination of the wires to locate the trouble, and can feel perfectly safe in doing so. In tunnel work the safety, speed and certainty of electrical firing places it so far in the lead as to leave no choice. There is no long wait for the blast to "go," and no doubt as to whether or not it exploded. The absence of smoke from the burning fuse is no small item. In excavating for buildings in crowded cities—and even here dynamite is now indispensable—the blaster can choose the most favorable moment for firing even a single shot, and is relieved of the fear that some one may approach the blast while the fuse is burning. He can clear the way for the blast, fire it and at once send the workmen back to their places.

The blaster who undertakes this work will require

a blasting machine, some heavy leading wire, connecting wire, insulating tape, and one electrical fuze for each hole to be fired.

Of blasting machines there are several kinds and sizes. The machines operated by a crank are usually of too small a capacity for anything except shooting wells or firing small blasts. Besides this there are two well-known types of machines, the "push down" and the "pull up," the terms being indicative of the manner of operating when firing. There is little difference between them—each being good—but the push down kind is perhaps the better known (Fig. 2). A No. 3 machine when in good condition will fire 20 to 30 fuzes at a time; a No. 4, 40 to 50 fuzes. Beyond this capacity there is but one machine made, the No. 5 pull up, which will fire 75 to 100 fuzes at a shot. If the blaster expects regularly to fire 25 to 30 fuzes at a shot, he would do well to choose a No. 4 machine, for the greater capacity lessens the chances of a misfire and a single miss might cost a great deal more than the difference in price.

Some of the push down batteries are made with three connection posts instead of two, the idea being to divide the blast into two circuits. Practical blasters have found this to be a useless complication, as

after which it is a good plan to carefully coat the coils with shellac.

Leading wire is used for connecting the battery to the electrical fuzes placed in the blast line. It is a heavily insulated copper wire put up in coils of 500 feet. Instead of this is sometimes used a double wire called a "blasting cable," which is somewhat easier to handle. This comes in coils of 250 feet. Connecting wire is a finer wire used for connecting between the holes. It is usually put up in 1 and 2-pound spools. Insulating tape is needed for protecting bare connections made underground or lying on wet ground.

Fig. 4 shows an electrical fuze in section. Into a blasting cap are inserted two copper wires held in place by a sulphur plug. The ends of the copper wires are bridged by a very fine and delicate wire, which is heated to combustion by the current of electricity which is forced through the circuit by the blasting machine. In the best makes of fuzes this bridge is made of platinum. The bridge is imbedded in finely chopped guncotton, which in turn communicates the flash to the charge of fulminate. Guncotton is used for priming because it is the most stable explosive known, besides lessens very materially the danger of breaking the delicate bridge. Some mak-

evidenced by the fact that nearly all such machines after having been used awhile, are found to have had the third post knocked off. The benefits of the three wire system are largely imaginary, while the trouble the third wire gets you into is real.

These blasting machines are simple dynamos and do not require to be recharged, as many suppose. With decent care they will last indefinitely. Good care counts for a great deal with them. They should be kept in a dry place, if possible, and the commutator and brushes frequently sandpapered. Don't use emery. No oil should be used on the commutator, but if it appears to be cutting, the armature should be taken out and the commutator turned and filed smooth and lubricated with graphite or by rubbing on the lead from a common lead pencil. The brushes should bear so tight that a decided resistance is felt when turning the armature with the fingers (Fig. 3). If the armature continues to spin after the completion of the stroke of the rack bar, the brushes do not bear down hard enough. The little slots in the commutator should be scraped out to free them from particles of copper which tend to short circuit the current and very greatly diminish the power of the machine. If the blasting machine is exposed to rain or stored for a long time in a very damp place, the coils of wire forming the fields and armature will take up enough water seriously to interfere with the working of the dynamo. The coils should be thoroughly dried by setting the machine on top of a boiler or in some place where it will thoroughly dry,

ers use gunpowder or other explosives instead of the guncotton. The copper wires leading from the cap are covered with two windings of cotton and further insulated by a tarry composition, which prevents short circuits being formed by moisture in the ground. The insulation is not strictly waterproof—in fact, such insulation is not required, although fuzes with rubber-covered wires will be made when the blaster thinks he must have them. The cost of the rubber-covered wires is necessarily very much higher than the regular insulation. Fig. 5 shows a cap ready for firing.

The standard fuzes are made with wires of various lengths—from 4 to 30 feet.

Consider the delicate nature of the bridge, and it will be apparent that the fuzes should be handled carefully. Roughly pulling the wires or tying a "half hitch" in them to fasten the fuze to a dynamite cartridge is very likely to put an unequal strain upon the wires which might dislocate the plug, break the bridge and not only cause that particular fuze to miss fire, but all the other fuzes in the circuit as well. Another reason for handling carefully is that the cap contains a charge of explosive which is very much more powerful than dynamite, and is extremely sensitive to heat and shock. As an illustration of its explosive force, a cap placed on end on a 4-inch pine board and fired will blow a hole through the board as clean as a rifle bullet would make.

The caps used in making the standard strength fuzes (sometimes erroneously called single strength)

are much more powerful than XXXX blasting caps. The standard strength fuzes are of ample power to explode any grade of ordinary dynamite. The double strength fuzes contain a stronger charge than even the XXXXX caps, and are intended to be used with gelatin dynamite, which is more difficult to explode than ordinary dynamite.

When all the holes to be fired at one time are loaded and tamped, separate the ends of the two wires in each hole and, by the use of connecting wire, join one wire of the first hole with one of the second, the remaining free wire of the second with one of the third, and so on to the last hole, making a continuous connection between the holes and leaving a free wire at each end.

There are several methods of connecting the wires. The common way and the best for all around use is the "series" connection, shown in Fig. 7. The blasting machines are designed and wound especially for this style of wiring, and the best results are obtained by its use. With the blast connected in this way, about one volt is required for each fuze and a current of two or three amperes is usually sufficient to fire a large blast.

Another is the "multiple" connection (Fig. 8), which requires approximately one ampere for each fuze to be fired, while a comparatively low voltage is sufficient. This is the best method to use when firing with the current from an electric light plant, for then there is an abundance of current—usually too much. Such a current turned on to a blast arranged in series does not work well, probably because it fires some of the first fuzes before sufficient current can reach all. With a multiple arrangement the current is bound to be evenly distributed. On the other hand, a blasting machine which would fire fifty holes in series could not be relied on to fire more than five arranged in multiple, because the quantity of the current would not be sufficient.

For very large blasts a combination of the two methods works nicely. Fig. 9 shows a good way to connect 100 to 125 holes.

It is necessary in making connections to have the wires well cleaned and twisted together tightly, after the manner shown. Merely hooking the wires together, as shown in lower wire (Fig. 10), is bad practice, and will surely lead to trouble, for it makes a very poor contact, and, besides, the wire is apt to slack up and leave no connection at all. Bear in mind that a considerable portion of the surface of the wires should be in actual contact—an area at least as large as the section of the fuze wire—and this can only be accomplished by twisting the wires together for at least  $\frac{1}{4}$  inch.

The charges having all been connected, as directed herewith, the free wire of the first hole should be joined to one of the leading wires, and the free wire of the last hole with the other of the two leading wires extending to the battery. The leading wires should be long enough to reach to a point at a safe distance from the blast—say 250 to 500 feet.

Connecting wire should be of the same size as the fuze wire. Leading wire should be at least twice as large.

To fire the blast with a push down machine, lift the rack bar to its full length and push it down with all force, bringing the bar to the bottom with a solid thud. With a pull up machine, stand with one foot on each of the projecting irons at the bottom of the box and, with the handle at its lowest point, pull up the rack bar with all possible speed. The current developed by either style of machine depends on the speed with which the handle is operated.

In tamping, material should be selected which cannot injure the wires. Large pieces of crushed stone often catch the wires and kink them. This may break the wires or scrape off the insulation and leave an opening for a short circuit. Should it be necessary to make a splice which would come below the surface, the bare connection should be covered with insulating tape. Connections between holes should be raised above the surface by resting the adjoining insulated wire on a block of stone or supporting it by a stick stuck in the ground after the manner of miniature telegraph poles. If connections are likely to touch bare ground, they must be covered with insulating tape. If by chance the wires should be grounded at some point, or imperfect connection has been made, the blast will usually fail to fire and the blaster must set about correcting the wiring. It sometimes happens that because of careless wiring two or more "grounds" may have been made, robbing some of the fuzes of sufficient current to cause them to miss.

Then, again, the insulation might have been peeled from the wires of one of the fuzes by careless tamping, making a partial short circuit, as shown in Fig. 11.

If but one-quarter of the current should leak across the short circuit, the remaining three-quarters passing through the cap might not be sufficient to heat the platinum bridge before the other fuzes in the line were hot enough to fire and break the circuit, as shown in Fig. 12. This kind of misfire most often happens with a weak battery. A battery giving a current considerably in excess of that actually required would in all probability fire such a fuze in spite of the leak.

With electrical fuzes to fire the shot, the way is easy for all sorts of special methods of loading which

would be impossible with fuses. Local conditions may be met by double charging holes with different grades of dynamite, and by other methods which will suggest themselves to the ingenious blaster. Suppose you have a high face with soft rock top and very hard rock at the bottom, a not uncommon condition. You have but to put some 60% dynamite in the bottom of the hole, a fuze and some tamping; then, say half way up, some 40% dynamite containing another fuze, and more tamping. In this way the bottom may be blown out clean and broken up properly, while the charge of 40% farther up will be sufficient to move the softer rock. After a little experimenting the strength of the two charges may be so regulated that the bottom will be blown out in advance of the top, the 60% being quicker than the 40% and the soft rock above pretty thoroughly mixed with the harder rock below by simply falling straight down upon it. This method is very effective in mixing the different kinds of clay often found in the upper and lower layers of a clay bank.

In attaching a fuze to a dynamite cartridge a hole should be made in the cartridge with a piece of wood, the cap inserted and tied securely in place with a string. This is more work than the other methods, but in the end it pays.

The practice of sticking the cap in the side of a cartridge and securing it by a half hitch of the wires is prolific of misfires and should be severely condemned. Such a half hitch very often results in peeled insulation and either leaves the wires in actual short circuit, or, disturbing the insulation, leaves an opening for water to complete the short circuit. A great many cases have been noted where wires have been actually broken by this half hitch. And, further, the sharp bending of the wires shatters the sulphur plug in the cap. This permits a strain directly on the fine platinum bridge and often breaks it. Disturbing the plug in this manner also leaves an opening for the water to enter the cap.

The cost of an electrical fuze is more than the cost of a blasting cap and sufficient common fuse to fire the same shot. But if you will take into consideration the time of workmen saved in the one case and lost in the other; the loss from misfires which could have been avoided; the saving of explosives resulting from simultaneous firing, which most authorities put at not less than 25%, the advantages are overwhelmingly on the side of the electrical way, to say nothing of the satisfaction which comes from the use of such a speedy, safe and reliable means of firing blasts.

### A Compact Transit.

The transit illustrated herewith weighs six pounds, the tripod five pounds. It is 8 inches high, with an outer diameter of the horizontal limb of  $4\frac{1}{2}$  inches. The achromatic telescope is  $6\frac{1}{2}$  inches in length and has a power of eighteen diameters. It has a patent screw focusing arrangement, rack and pinion move-

A Compact Transit.

ment, and the telescope axle is fitted with clamp and tangent screw with opposing spring. The verniers are fitted with ground glass reflectors. It is manufactured by Queen & Co., 1006 Chestnut street, Philadelphia.

In the distillation of zinc from cyanide precipitate it is proposed that the precipitate should be dried, mixed with lead and charcoal, and retorted. If mercury be present, it can be recovered at the beginning of the distillation, the zinc being later condensed as dust suitable for further use as precipitant. The residuum containing the gold and silver should be smelted with lead in a furnace like the ordinary cupellation furnace, iron ore and silver being added in such proportions as to give a fluid slag, from which the lead separates. The slag should be skimmed off and the lead cupelled in the usual way, the resulting litharge being used in the next operation.

### Tellurium in the Hauraki Goldfields.\*

Written by F. B. ALLEN.

New Zealand has often been quoted by metallurgists and others as one of the countries in which tellurium is found, and locally it has been recorded that appreciable quantities of tellurium have been met with in the Thames and surrounding districts. However, specimens containing tellurium which have been obtained on this field have not been preserved, and their scarcity to-day points to the fact that tellurium is not here abundant.

To ascertain its distribution, analyses and assays have been made by the author on a large number of ores, the results of several of which are given below.

In sampling reefs for assay purposes, one of the troubles is the difficulty of obtaining representative samples, especially where the gold is coarse and patchy, and in many cases it is practically impossible to obtain a correct valuation of the Thames reefs from assay samples. The only reliable method is to actually treat a large quantity of the ore, and value the slimes and tailings by assay. There is, however, no criterion that the next 100 tons will yield results at all corresponding with those of the previous 100 tons.

Similar trouble has been experienced in the present tests, and it must be conceded that, although several analyses from a mine may each show no tellurium, this substance may be present in other parts of the mine. On the other hand, a single analysis will sometimes establish the fact of its existence in the ore.

As the economic importance of the occurrence of tellurium in a mining district is intimately connected with the amount of bullion found near or associated with it, and would be practically nil if the tellurium were not found along with the gold and silver in the reef, the method adopted for the identification of tellurium on the Hauraki Goldfields has been to obtain and analyze the rich sulphide ores in each district. For if the tellurium were not found in conjunction with the richest values it would probably be absent from the mine, or, if present, would have little prejudicial effect on the recovery of the bullion in the milling process.

Although unable to obtain any samples of ore containing a high percentage of tellurium in this district, the author has from time to time come across evidences and traces of this substance, and has located it in a number of mines and localities where hitherto it had not been recognized.

In every instance in which tellurium was found there was so small a percentage, and it was associated with such a comparatively large amount of base sulphides, that it was impossible to determine in what combination the tellurium existed, and consequently no attempt is here made to name the different tellurium-bearing minerals on the peninsula. It is, however, noteworthy that copper was present in greater or less quantity in every ore in which tellurium was detected.

Tellurium has been found by the author at the following places:

Coromandel.—Quartz containing 25% mispickel. Assay: 200 ounces gold per ton; 90 ounces silver per ton. This ore contained a little tellurium, the amount of which was not estimated. A considerable quantity of the ore was roasted without loss of bullion.

Tapu.—Quartz containing dense iron and copper pyrites. Assay: 24 ounces gold per ton; 250 ounces silver per ton. Analysis showed the presence of 7½ ounces of tellurium per ton, i. e., approximately, 3% of the bullion in the ore.

Waiomo.—Small sample of white quartz from the Gem mine, showing sulphides of silver, but no visible gold, along a dark band. Assay: 15 ounces gold per ton; 600 ounces silver per ton; 12 ounces tellurium per ton, equal to 2% of the bullion.

Waiomo.—Monowai ore containing quartz, sulphides of iron, copper, lead and zinc, with a trace of antimony. Assay: 4 ounces gold per ton; 30 ounces silver per ton. Tellurium was present in small quantity, amounting to less than 1% of the bullion.

Broken Hill, Waiomo.—White quartz with blue-black specks containing iron and copper pyrites and sulphides of silver. Assay: 2 ounces gold per ton; 40 ounces silver per ton. The ore contained 4 ounces of tellurium per ton.

Similar samples containing copper pyrites from Tararu creek contained a small amount of tellurium, and Maratoto ore yielded a little. One sample from Maratoto taken many years ago gave a much higher percentage.

The following indicate the nature and value of some of the samples in which no tellurium was detected:

Waihi.—Dense iron pyrites containing quartz and copper pyrites. Assay: 24 ounces gold per ton; 760 ounces silver per ton.

Jubilee.—Friable quartz in cavities of hard white quartz. The ore contained blue veins of sulphide of silver as well as copper carbonate. Assay: 8 ounces gold per ton; 150 ounces silver per ton.

Komata.—White quartz containing a black band, in which were copper minerals and gold. Assay: 600 ounces gold per ton; 160 ounces silver per ton.

Karangahake.—Concentrates from the Woodstock.

\* Abstract Trans. Australasian Inst. Min. Engrs.

Assay: 2 ounces gold per ton; 256 ounces silver per ton. Although the mine occasionally produces a little cobalt and nickel, none was found in these concentrates.

Great Barrier.—White quartz containing iron pyrites and the blue veins of sulphide of silver. Assay: 2 ounces gold per ton; 200 ounces silver per ton. A considerable amount of selenium was detected in this one, but no tellurium.

In connection with this, the sulphur-dioxide method of the separation of selenium and tellurium was not found satisfactory, and ferrous sulphate was used as a means of separation of the two substances.

Thus tellurium has in these experiments been found along a line stretching from Coromandel to Maratoto, but nowhere to the east. Numerous samples from Tairua, Waitekauri, Waihi and other mines of Karangahake failed to show any tellurium, so that it may fairly be said that in the ore coming to grass from these districts at the present time there is little or no tellurium.

That analyses of rich ores from every part of the district have shown tellurium in only a few instances, and then only in small quantities, indicates that this substance, during late years at any rate, has not been mined along with the auriferous quartz in sufficient quantity to exercise a prejudicial effect on the extraction of gold.

## The Mines of Cripple Creek, Colo.\*

NUMBER II.

Written by W. LINDGREN and F. L. RANSOME.

STRUCTURAL CHARACTER OF DEPOSITS.—With few exceptions the ore bodies, of whatever shape, are casually connected with fissures, and most of them constitute fissure veins of various types. The fissure system of the district appears to radiate from a point near the northern limit of the volcanic area. In the eastern part the prevailing directions are northwest or north northwest, gradually changing to a northerly strike in the southern portion and to predominant north-northeast or northeast courses in the western side of the district.

Individual veins are rarely over half a mile in length, but linked-vein systems often extend for a

by replacement and recrystallization of the country rock—usually granite. These types are not always sharply distinct, but may be connected by deposits of intermediate character.

All the ore bodies, of whatever type, exhibit certain common features which serve to distinguish the deposits of Cripple Creek from those of most other mining districts. In the first place, the actual openings in the rocks available for the deposition of ore are, as a rule, remarkably narrow. In the second place, the amount of material carried in the mineralizing solutions and deposited as gangue and ore minerals was comparatively small. In consequence of

SHEETED VEINS.—The mineralized sheeted zones constitute the most characteristic deposits of the district and occur in practically all the rocks, although particularly common in breccia. They consist of a varying number of narrow, approximately parallel fissures, together composing a sheeted zone that may range from a fraction of a foot to 50 or 60 feet in width. Such uncommonly wide zones of fissuring, however, can usually be resolved into two or more sheeted zones lying so close together that the whole constitutes for practical purposes a single ore body. Usually the sheeted zones are from 2 to 10 feet in width. In other cases the fissures may be very

Vindicator Mine, Cripple Creek, Colo.

El Paso Mine, Cripple Creek, Colo.

mile in the same direction. The dip is generally very steep. The movement along these fissure planes appears in all cases to have been very slight. The fissures charged with ore are sometimes simple veins with one fracture plane; much more commonly, however, they are composite veins or lodes which consist of several closely spaced and frequently linked fissures, all more or less ore bearing. A better expression for this structural type as it appears in Cripple Creek is the term "sheeted zone."

TYPES OF DEPOSITS.—The most important types of auriferous ore bodies occurring in the district are:

1. Tabular in form and strictly following simple fissures or sheeted zones. A subtype comprises lodes in which the sheeted zone follows "basalt" or phonolite dikes.

2. Irregular bodies adjacent to fissures and formed

these two conditions, the district contains no such massive veins, solidly filled with quartz or other vein minerals, as are characteristic of the San Juan region in Colorado or the mother lode region in California. Even the small fissures of the Cripple Creek district are rarely completely filled, but exhibit a characteristic open or vuggy structure. Where the fractures are of unusual width, or where the rocks are extensively shattered, as in the Midget and Moose mines, the small volume of available vein matter is particularly noticeable. The walls of such fractures and the fragments of the shattered rock are usually merely coated with a thin deposit of quartz, fluorite and other minerals. As the rich tellurides were usually among the minerals last to form, and are particularly abundant on the walls of the vugs, it is probable that had quartz, fluorite, or other gangue minerals been more abundantly deposited the ores would have been of much lower grade.

numerous, the rock for a foot or more in width being divided into thin parallel slabs, while on each side of this medial portion the fissures become farther and farther apart as the lode grades into the normal country rock of the vicinity. In still other cases there may be two main fissures, 3 or 4 feet apart, accompanied by more or less irregular fracturing of the intervening and adjacent rock. As a rule the fissures are mere cracks, showing no brecciation, slickensiding, or other evidence of tangential movement of the walls. Usually the tellurides are exclusively confined to the narrow fissures and cracks, and do not, in this type of deposit, in any sense constitute a replacement of the country rock. The rocks in the vicinity of the fissures are partly replaced by dolomite, pyrite and a little fluorite; the telluride ores, however, do not share this propensity, but coat the open fissures, associated with a little quartz and fluorite. The fissures are not, in general, planes of

\* Abstract Bull. 254, U. S. G. S.

faulting. Appreciable movement has undoubtedly occurred in some instances, but the displacement probably rarely exceeded 1 or 2 feet.

Although found most abundantly in the breccia or trachytic phonolite, sheeted zones and single fissures are often well developed in the granite, as in the El Paso, C. K. & N., and Gold Coin mines. While in some of these lodes the ore minerals are as plainly confined to the fissures as in the breccias, in other cases the ore to some extent permeates the granite alongside the fissure, this constituting a deposit intermediate in nature between types 1 and 2. They also frequently follow phonolite dikes, the general tendency of these dikes to develop a platy parting parallel to their walls being particularly favorable to the production of a well-defined sheeted zone when the direction of fissuring happens to coincide with that of the dike.

The metasomatic alteration accompanying these sheeted zones is surprisingly slight, and consists of a partial replacement of the breccia, phonolite, trachytic phonolite, or "basalt" by dolomite and pyrite accompanied by a small amount of sericite and a little secondary potash feldspar. But even in the most altered rock the newly formed minerals rarely form more than a small percentage of the rock mass. The alteration in granite exhibits a somewhat different phase, described in a subsequent paragraph.

Not all the sheeted zones carry ore, nor is the ore of a productive sheeted zone necessarily coextensive with the fissuring. The ore occurs in pay shoots up to 2000 feet in length and 1000 feet in depth, but usually very much smaller than is indicated by these limits. The boundary between the ore and the barren portions of the lode can be determined, as a rule, only by assays. No single factor that can account for the localization of the ore in these pay shoots has been discovered. In some mines the pay shoots occur where the lode is intersected by cross fissures; in other mines no such relation exists. In some mines ore occurs where the fissures pass through phonolite dikes; in other mines the lode, elsewhere productive, becomes barren when it enters phonolite; while in still others the presence of the phonolite has had no apparent influence upon ore deposition. It thus appears that the occurrence of two or more favorable factors is necessary to determine the position of a pay shoot in a lode. The discovery of these factors is one of the unsolved problems connected with the Cripple Creek district.

## Methods of Renewing Old Timbering at the Dives-Pelican Mine, Silver Plume, Colo.

NUMBER II.

Written by J. F. McCLELLAND.

**REOPENING CAVED DRIFTS.**—This work is more difficult and dangerous than that of replacing old timber. The simplest case occurs when the back of the drift will stand unsupported for a short time. Enough of the broken ore is removed to make room for a new set, which is then put in place, braced and lagged. The top lagging poles are put on first. In many instances, however, the ore is dry and shows a strong tendency to run. It then becomes necessary to resort to "spiling."

The timbering is first brought up as near as possible to the caved portion of the drift in the manner already described, and the forward ends of the lagging poles are blocked up on the last set as shown at a, Figs. 4 and 5. The blocks used are sawed from lagging poles and are about 6 inches long. Smooth lagging poles, 4 or 5 inches in diameter, and roughly sharpened at one end, are used for spiling poles. The point of one of these is held against one of the blocks (a, Fig. 5) and the pole is driven forward with a sledge. This, of course, knocks out the block, but the spiling pole supports the lagging above. All of the blocks are replaced in the same way, the spiling being driven ahead into the caved material as far as possible. Wedges (b, Fig. 6) are inserted to keep the spiling at a proper inclination. Under the protection of these spiles some of the caved material is removed, the spiles are driven farther ahead, and a false set (c, Fig. 6) is erected from 2 to 3 feet ahead of the main set. The work then has the appearance shown in Fig. 6. Next the spiles are driven home and the new set is erected as shown in dotted lines. The next spiling poles can then be started under the cap of the false set and over the cap of the main set.

In carrying out this work care must be taken to keep all of the spiling poles even and at the same inclination. They should be given sufficient pitch to insure plenty of room above the main set for the insertion of the next series of spiling poles. The poles themselves must be cut longer than the ordinary lagging pole. Where the sets are placed 4 feet 8 inches center to center, a 6-foot spiling pole is not too long.

The presence of large rocks may cause a great deal of trouble. Where possible the spiling poles are driven over a large rock. If this can not be done,

the rock must either be split up with a gad or a sufficient amount of the caved material removed from underneath to allow it to fall.

As a general rule, the walls of the drift do not require spiling and they are lagged in the ordinary way, after the roof is completed, and the new set in place. If necessary, they may be spiled in a similar manner. For the sake of clearness, the side lagging has not been shown on the drawings.

An interesting variation of this method is shown in Fig. 7. Here the back of the drift caved unexpectedly just after a new half set had been put in place and lagged. The caved material ran freely and spiling became necessary. The pressure of the overlying

FIG. 4.

FIG. 5.

FIG. 6.

FIG. 7.

ing ore was so great, however, that the ends of the lagging poles could not be raised to give room enough to start spiling poles. This difficulty was overcome by cutting away a portion of the ends of two adjacent lagging poles, directly over the cap. A spiling pole was then driven through the hole formed in this way (Fig. 7). The next lagging and the remaining portion of the first lagging were then cut away in the same manner, and a second spile was driven in alongside the first. By repeating the process spiles were driven in across the whole roof. These spiling poles were cut so long that their rear ends projected behind the cap, and supported the forward ends of the lagging, thus avoiding any weakness due to cutting the lagging away where they rested on the cap.

The same device is resorted to in repairing caves of one or two sets in heavy ground.

The method of spiling as above described answers satisfactorily for the ordinary conditions encountered, but occasionally ground is met with which runs so freely that the face of the drift must be supported before room enough can be obtained to erect the new set. Breast boards are then used to hold back the face, as shown in Figs. 11 and 12. In a particular case observed the hanging wall was strong enough to carry timber in a hitch, while the foot wall was much softer. Spiling poles 7 feet long were driven in and a false set (e, Fig. 9) was erected as usual. As the poles were driven past the false set no attempt was made to excavate the whole face—only a small portion of the caved material directly under the spiles was taken out. A 6-inch timber (a, Figs. 9

FIG. 9.

FIG. 11.

FIG. 10.

FIG. 12.

and 10) was then put in place, with ends supported by hitches cut in the walls. Near the foot wall end a post b was set up and given a firm footing on a 2-inch block imbedded in the ore. This post was braced back to the false set. More of the caved material was then removed and the pole c, Figs. 11 and 12, was put in and braced back to the post b. The ends of this pole also rested in hitches. Breast boards of 1-inch plank, 10 inches wide and 24 inches long, were driven into the caved ore behind the pole c, as shown in Figs. 11 and 12. These boards served to support the face sufficiently to allow excavation to proceed to the point d, where a second pole and series of breast boards could be put in.

At this point a second post similar to b, but longer, was set up under the timber a, near the center of the drift, and the poles c and d were braced to it. The post b was then removed and a longer one substituted. By repeating these operations the whole face of the drift was opened up and the new set was erected just in front of the breast boards.

The presence of old and decayed timber in the caved ore is often of material assistance in preventing the ore from running while carrying out the work. Obviously the method may be modified for use where both walls are too soft to carry timbers in hitches.

It is impossible to estimate the cost of doing work like spiling and breast boarding, owing to the great irregularity in the conditions encountered. A set may sometimes be put up in a single day, while another will take a week for its completion. In all cases, however, this work is much more expensive than the replacement of old timber.

(TO BE CONTINUED.)

# Mining and Metallurgical Patents.

PATENTS ISSUED JANUARY 17, 1905.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

**SAFETY DEVICE FOR MINE SHAFTS.**—No. 779,535; N. W. Dickerson, Derwent, Ohio.

Combination with elevator shaft, landing, and elevator car movable in shaft; of movable device for stopping car and preventing passage of same toward shaft, means for moving device to and normally holding it in position to bar passage of car, trigger arranged to be engaged by elevator car, connection between trigger and movable device for moving latter by former; connection comprising parts one of which is movable out of engagement with other to break connection, and movable device arranged in advance of first mentioned movable device and adapted when operated by car to move movable part of connection out of engagement with complementary part of connection.

**SMELTING FURNACE.**—No. 779,953; A. E. Manchester, Newburg, N. Y.

Combination with furnace and forehearth, of interposed separable cut-off valve arranged to open and close communication between two and means for removably securing one member of valve to furnace, other member of valve to forehearth and two members of valve together.

**MORTAR FOR STAMP MILLS.**—No. 779,521; M. P. Boss, San Francisco, Cal.

In mortar for stamp mills, having formed in it mortar bottom, and having columns at opposite ends of diameter of bottom, columns converging downwardly to flange of like internal slope which surrounds bottom, correspondingly tapered body shell detachably fitted within columns and flange, vertical keys engaging top of body shell, and cross keys slidably secured to columns and engaging lower ends of vertical keys, to detachably secure body shell to columns.

**WELL DRILLING MACHINE.**—No. 779,671; F. E. Simpkins, Allegheny, Pa.

Combination of shaft, arm mounted thereon and adapted interchangeably to turn with shaft or independently, spudding mechanism operatively connected to shaft, walking beam having detachable connection with arm, and means for oscillating arm.

**CONCENTRATOR TABLE.**—No. 780,031; F. E. Foster, Clifton, Ariz.

Table for reciprocatory concentrators having plurality of sets of riffles, upper edges of which are disposed in the same plane, each set being arranged to overlap next lower set, and openings being disposed within line of termination of riffles above them.

**ROASTING FURNACE.**—No. 780,115; A. R. Meyer, Kansas City, Mo.

Furnace having hearths and shaft or pipe with stirrer arms extending over hearths combined with water supply pipe at top of shaft, and conduits arranged to direct water from pipe downward along inner face of shaft.

**AMALGAMATOR.**—No. 780,109; B. A. Langridge, Boulder, Colo.

Amalgamator, comprising exterior casing having feed pipe entering upper portion, fan-shaped spreader plates located in upper portion of casing and each being fluted or bent from inner corners outward to outer edges, inner corners lying directly adjacent to inlet pipe and flutes or bends gradually increasing in width and depth toward discharge edges of spreader plates, two additional triangular plates located between spreader plates at each side of inlet pipe, all of plates forming low pyramid, and amalgamating devices below same.

**METHOD OF CLEANSING OIL WELLS.**—No. 780,279; W. E. Gardner, Pittsburg, Pa.

Method of cleansing oil wells which consists of first closing bore well at suitable point adjacent to upper end of oil-bearing strata and subjecting walls of bore thereof in oil-bearing strata to action of heated fluid.

**FURNACE FOR ROASTING ORES, ETC.**—No. 780,387; W. W. Tobey, Iola, Kans.

In kiln for roasting ores, combination of furnace proper, traveling members disposed adjacent thereto, rake bars connected with traveling members, shields secured to and encircling portions of rake bars that enter furnace, rake blades connected with rake bars and shields and adjustable vertically and angularly, and means for actuating traveling members.

## MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

According to the twentieth annual report of the U. S. Geological Survey on the mineral resources of the United States, the mineral production for 1903 was \$1,419,721,569, as compared with \$1,260,509,738 in 1902, a gain of 12.63%. Iron and coal continue the most important mineral products. The value of the iron in 1903 was \$344,350,000; the value of the coal \$503,724,381. The gain in total value is due to the large increase in non-metallic productions. The metallic products showed a decrease of from \$642,258,584 in 1902 to \$624,318,008 in 1903, a loss of \$17,940,576, and the non-metallic products showed an increase from \$617,251,154 in 1902 to \$794,403,561 in 1903, a gain of \$177,152,407. To these products should be added estimated unspecified products, including building, molding and other sands, molybdenum and other mineral products, valued at \$1,000,000, making the total mineral production for 1903 \$1,419,721,569. The gold production was \$73,591,700 and silver 54,300,000 ounces of \$29,322,000 commercial value.

According to the United States Geological Survey, the mineral products of the United States for 1903 were as follows:

Metallic.	Quantity.	Value.
Pig iron, spot value.....	18,009,252 long tons.	\$ 344,350,000
Silver, coin value.....	54,300,000 troy ounces.	70,200,000
Gold, coin value.....	3,569,000 troy ounces.	73,591,700
Copper, value at New York City.....	698,044,517 pounds.	91,506,000
Lead, value at New York City.....	230,000 short tons.	23,500,000
Quicksilver, value at San Francisco.....	159,219 flasks.	16,717,995
Aluminum, value at Pittsburgh.....	7,500,000 pounds.	1,544,634
Antimony, value San Francisco, short tons.....	3,128	2,284,900
Nickel, value at Philadelphia.....	114,200 pounds.	548,433
Platinum, value (crude), San Fran., troy ozs.....	110	45,900
		\$2,080

Total value of metallic products..... \$ 634,318,008

### Non-Metallic (Spot Values).

Bituminous coal.....	282,749,348 short tons.	\$ 351,687,633
Pennsylvania anthracite.....	66,613,454 long tons.	152,036,448
Natural gas.....	35,815,360 barrels.	35,815,360
Petroleum.....	100,461,337 barrels.	94,694,050
Brick clay.....	15,000,000 barrels.	15,000,000
Cement.....	29,859,140 barrels.	31,131,341
Stone.....	67,990,483 short tons.	67,990,483
Corundum and emery.....	2,542 short tons.	61,102
Crystalline quartz.....	8,938 short tons.	70,008
Garnet for abrasive purposes.....	3,950 short tons.	132,500
Grindstones.....	721,446 short tons.	721,446
Infusorial earth and tripoli.....	9,219 short tons.	76,273
Millstones.....	52,552 short tons.	52,552
Oilstones, etc.....	366,857 short tons.	366,857
Arsenious oxide.....	611 short tons.	36,696
Borax, crude.....	34,430 short tons.	61,400
Bromine.....	568,500 pounds.	167,580
Fluorspar.....	42,523 short tons.	213,617
Gypsum.....	1,041,774 short tons.	3,792,942
Lithium.....	1,155 short tons.	23,425
Marls.....	34,211 short tons.	22,521
Phosphate rock.....	1,581,576 long tons.	5,319,284
Pyrite and sulphur.....	423,127 long tons.	1,109,818
Salt.....	18,908,089 barrels.	5,286,609
Barites, crude.....	50,397 short tons.	152,150
Cobalt oxide.....	120,000 pounds.	120,000
Mineral paints.....	62,122 short tons.	646,222
Zinc white.....	62,902 short tons.	4,801,718
Asbestos.....	887 short tons.	16,760
Asphaltum.....	101,255 short tons.	1,005,446
Bauxite.....	48,027 short tons.	171,306
Chromic iron ore.....	1,000 long tons.	61,102
Clay (all other than brick).....	1,650,835 short tons.	2,640,012
Feldspar.....	41,891 short tons.	256,733
Fibrous talc.....	60,230 short tons.	421,600
Flint.....	55,293 short tons.	156,947
Fuller's earth.....	30,693 short tons.	190,277
Glass sand.....	823,014 short tons.	855,828
Mica (crystalline).....	4,538,159 pounds.	2,255,554
Graphite (amorphous).....	16,591 short tons.	225,554
Limestone for iron flux.....	12,029,719 long tons.	5,423,732
Magnetite.....	3,774 short tons.	10,555
Manganese ore.....	2,825 long tons.	25,325
Mica sheet.....	90,100 pounds.	17,128
Mica, scrap.....	1,693 short tons.	41,990
Mineral waters.....	51,243,550 gallons sold.	9,041,078
Monazite.....	862,000 pounds.	64,690
Zircon.....	3,000 pounds.	570
Precious stones.....	321,400 short tons.	321,400
Pumice stone.....	885 short tons.	2,665
Talc and soapstone.....	26,671 short tons.	418,660
Uranium and vanadium.....	19 short tons.	5,625

Total value non-metallic mineral products..... \$ 794,403,561  
Total value of metallic products..... 634,318,008  
Est. value mineral products unspecified..... 1,000,000  
Grand total..... \$1,419,721,569

\*Not including \$6000 worth of platinum reported as contained in slimes from copper ore from the Ramblar mine, Wyoming.

†Included under pyrite in 1901, 1902 and 1903.

[Not including value of sixty short tons of cobalt ore produced in Idaho.]

### ALASKA.

The Portage Mountain M. Co., office 322 Union street, Seattle, Wash., has started work at the head of Duncan canal, near Wrangell. C. E. Jury is Alaska manager.

During May, June, July, August and September, 1904, C. W. Purington of Denver, Colo., and S. Paige journeyed through Alaska investigating for the United States Geological Survey the costs and methods of gold-placer mining in the Territory. For the purpose of making comparative observation, he also visited the Atlin district of British Columbia and the Klondike gold fields of the Yukon Territory. In studying the conditions which affect placer mining in our northern possessions, he was impressed with the inadequate means of communication between the different parts of the Territory. The gold mining which has been done in the interior of Alaska has been conducted in spite of difficulties of transportation which seem hardly credible. His conclusion is that highways must be constructed in Alaska if the Territory is to develop as it should. Owing to its varied topography, Alaska may be divided, from a highway standpoint, into three provinces—the south coast province, the central Yukon province and the Seward peninsula province. The portions of Alaska represented by the Alaska peninsula and neighboring islands and the Copper River basin, north of Prince William sound, were not especially considered by Mr. Purington, as those parts of the Territory appear to have no present need of expensive routes of communication. In general, it may be said, however, that the cost

of construction in the Alaska peninsula is the same as in the Seward peninsula, and the cost in the Copper River basin the same as in the central Yukon province. There is a great difference between the topography of the mountainous southeast coast and that of the rich placer districts in the flat interior, and the expense of road building in Alaska varies accordingly. Near Dawson, in the Yukon Territory of Canada, standard highways have been constructed by the Canadian Government at a cost of \$1500 to \$3300 a mile. The annual maintenance of such a road costs \$350 a mile. This locality offers the most instructive lesson in practical highway construction in the north, and affords a striking contrast in this respect to the adjacent American domain. The average cost of construction for sled or winter trail in this Territory is from \$250 to \$350 a mile. These trails can be maintained for about \$25 a year. Previous to the construction of the wagon roads, transportation charges per 1000 pounds from Dawson to Grand Forks, a distance of 12 miles, amounted to \$7. The same amount of merchandise is now transported the same distance for \$1. The improved conditions thus mean a direct benefit to the miner of at least 600% on all supplies and machinery freighted by wagons over first-class roads. It is estimated that standard highways, similar to those in the Canadian Yukon, could be constructed in the central Yukon province in the Tanana, Birch Creek and Koyukuk districts for from \$1200 to \$3000 a mile. Such roads could be maintained on a yearly allowance of \$350 a mile. Sled or winter trails might be constructed in the same district for \$300 a mile. A. H. Brooks has suggested the following routes for Government roads in the central Yukon province of Alaska: 1. A road from Eagle to the Tanana, the Chistochina, and to Valdez, on the coast, a distance of 400 miles. 2. A road to extend from Circle, on the Yukon, through the Birch Creek and Fairbanks districts to the Tanana, a distance of 150 miles. 3. Rampart, on the Yukon, to be connected with the mouth of Baker creek, on the Tanana, by a road which would open up the Minook and Baker districts, a distance of less than 50 miles. 4. About 100 miles of road to be built in the Koyukuk region, to connect the gold-bearing creeks with the head of steamboat navigation on Koyukuk river. It is believed that these roads would form a system of main arteries by which most of the placer fields could easily be reached, and that the production of the mines would thereby be so much increased as to fully justify the expense. In the central and western portions of Seward peninsula, that is in the Nome, Solomon, Council, Topkok, Kugrook, Teller and York districts, any projects of installation of roads must take into account the entire absence of native timber. The cost of building the narrow-gauge railways in use there was \$6000 a mile, exclusive of rolling stock. The cost of wagon roads of the Dawson type would rarely fall below \$4000 a mile. Considering the comparative cheapness with which railway material can be hauled at various points on Seward peninsula, it is likely that short lines of railway will continue to be built by private enterprise to supply the several inland mining communities. In this part of the Territory the Federal Government should aid in the construction of tramways rather than railroads. Mr. Purington makes the suggestion that narrow-gauge pole tramways laid over the tundra might in some cases be used in parts of Seward peninsula for long hauls. On account of the mountainous character of the south coast province, the construction of wagon roads there is so expensive that it is not likely that they will be built except as heretofore, by private enterprise, to accommodate individual mining properties. The winters are extremely severe in the higher mountains. In the construction of the White Pass & Yukon Railway, 110½ miles in length, 1500 men were employed for a period of twenty-six months. The average cost of removing snow from the tracks in the course of a season is \$75,000.

### ARIZONA.

The estimated output for 1904 of most prominent copper properties in Arizona is:

	Pounds.
Arizona Copper Co.....	28,000,000
Calumet and Arizona.....	21,000,000
Copper Queen.....	58,000,000
Detroit Copper.....	18,000,000
Old Dominion.....	16,000,000
Shannon Copper.....	12,000,000
Troy Manhattan.....	500,000
United Verde.....	34,000,000
Small companies, custom smelters and products of ores shipped out of the territory in excess of importations.....	10,000,000
Total.....	200,500,000

### Cochise County.

(Special Correspondence).—The flue dust chambers of the Bisbee smelter are being demolished and the metal in the smoke and dust deposits are being recovered. Scaffolding has been erected between the walls and the work of getting the brick partitions down is proceeding with safety as well as speed. As the debris is cleared away the amount of flue dust continues to increase and several cars of this valuable material will soon be ready for shipment to the smelter for treatment. Assays of the dust show copper values ranging from 12% to 36%, with gold and silver. Assays for gold have shown values of \$20 to the ton. The Huachuca M. Co., near Bisbee, is about to build a 75-ton plant. Smith, Vanderman, Holtz & Cobb have bonded their interest in eight claims, near Paradise, to W. G. Rice of Houghton, Mich., for \$7000 for two years, Rice to begin work within sixty days. Bisbee, Jan. 24.

### Graham County.

(Special Correspondence).—The Tri-Bullion Smelting & Development Co. of Chicago, who are operating the Starlight group in Kelly gulch, 9 miles south of San Carlos, have shipped five cars of ore netting \$1000 per car, from the Ryan shaft. The tunnel on the Starlight mine is in 1400 feet. This tunnel furnishes an abundant supply of water for reduction purposes. The company will build in Kelly gulch a concentrating plant of fifty tons daily capacity by which the gold, silver and lead values will be saved. As the copper in the ore is carbonates and oxides the company will store the tailings and later erect a leaching plant to extract the cop-

per values. H. Paschal is president and general manager; J. P. Hendrick, secretary and treasurer, and W. J. Nicholson, superintendent. San Carlos, Jan. 23.

### Gila County.

The Arizona Commercial Co., with properties adjoining the Old Dominion in Globe, has been reorganized as the Arizona Commercial Copper Co. They will purchase the Matamora group, adjoining the Arizona Commercial, and will build a 1½-mile narrow gauge railroad to connect with the Gila Valley, Globe & Northern and the Old Dominion railroads. A smelter site has been obtained. Superintendent W. S. Sultan has started work and will increase the force. N. S. Amster of Boston is consulting engineer.

### Maricopa County.

(Special Correspondence).—The Black Canyon M. Co. has sold its property in the Black Canyon mining district to the Gy-Zo-Chemical Co. for \$50,000, and the new company, capitalized at \$1,000,000, has already expended \$30,000 in developments and improvements on this property which consists of six geysers, the source of the remarkable product that is, throughout the West, being introduced to replace antiplogistine. Maricopa county has built a wagon road to the property, 50 miles from Phoenix. The president is W. Banning and the treasurer, H. Banning of Los Angeles, Cal. M. N. Esky, the secretary, is manager of the Pacific hospital in Los Angeles and was the original manufacturer of antiplogistine.

Phoenix, Jan. 23.

### Pinal County.

(Special Correspondence).—The Troy-Manhattan Co., at the Buckeye shaft at Troy, is putting in two large boilers fitted for burning oil. The oil will be hauled 7 miles from Kelvin, the nearest point on the Phoenix & Eastern Railroad. C. H. Cutting is general manager and T. Kavanaugh, superintendent. Kelvin, Jan. 23.

### Yavapai County.

(Special Correspondence).—The mill of the Congress mine of the Con. G. M. Co., at Congress, has been closed down until further development work can be carried on. The company is working a cyanide plant to full capacity to clear up all the values in the old product, and is working in shaft No. 5 night and day, being down 1875 feet, going at the rate of 27 feet per week. In this shaft 4000 gallons of water are handled each day. The water is pumped to the surface and there turned to good account at the large cyanide tanks. The company has an unlimited amount of low-grade ore, which runs about \$4 to the ton, but under present conditions and facilities it does not pay to work this.

Congress, Jan. 24.

### CALIFORNIA.

PRODUCTION OF GOLD, SILVER AND COPPER IN CALIFORNIA IN 1903, BY COUNTIES.

COUNTIES.	Placer	Gold.	Placer	Silver.*	Copper	Total

Grand totals.....		\$16,300,653		\$498,412		\$19,340,446

\* Commercial value.

Total value of copper was \$2,533,355. Butte county produced \$210 in platinum, Humboldt \$362, Placer \$280, Trinity \$100; total \$952. Of the total of 166,946 pounds of lead, valued at \$7074, Inyo county produced 161,185 pounds, Mono 4720 pounds, San Bernardino 802 pounds and Tuolumne 236 pounds. These are included in the totals.

Regarding the gold and silver production of California for 1903, C. G. Yale in a United States report says returns received by the United States Geological Survey show California to have produced in 1903 gold to the value of \$16,300,653; silver (commercial value), \$498,412; copper, \$2,533,355; lead, \$7074; platinum, \$952; total, \$19,340,446, showing a decrease in gold product of \$491,447 and an increase in silver product of \$20,988, making a total decrease of \$470,459 as compared with 1902. This loss in annual product may be attributed chiefly to labor strikes at various large producing gold mines and copper mines producing gold, which caused the enforced idleness of such mines for periods of from one to three months. These troubles were not confined to any one section, but occurred in the mother lode counties, where many of the largest producers are situated, in Kern county, to the south of San Francisco, and in Shasta county, to the north. The mines ultimately resumed operations, though several have had to employ non-union men and are not working the same force as for-

merly, work being thus more or less hampered. The most noteworthy feature in connection with the gold production in California is the marked and rapid advance of the gold dredging industry. The total returns from the dredgers operated in 1903 were \$1,475,749. This result was obtained from twenty-five machines operating at Oroville, Butte county, three in Sacramento county, one in Siskiyou, one in Trinity and one in Yuba. Of the total for 1903, the sum of \$1,329,998 came from Butte county, the center of the dredging industry. The number of dredgers in the first part of 1904 at Oroville was twenty-seven, and in the summer of that year two of the largest dredgers in the State were installed between Marysville and Smartsville, on the Yuba river. Others have been built in Calaveras, Shasta and Trinity counties, and more are being constructed at different points. Ground suitable for dredging purposes is being prospected in many counties of the State, and is in great demand at prices ranging from \$500 to \$3000 per acre, according to prospective value. For the first time in the history of the State the output of the dredgers has exceeded that of the hydraulic or the drift mines. This fact alone shows the rapid advance of this branch of gold mining. The hydraulic mines produced in 1903 the sum of \$872,812, and the drift mines \$905,679. The dredger output exceeded each of these and came within about \$300,000 of equaling the product of hydraulic and drift mines combined. The principal section of hydraulic mining has changed of late years, and is now in Trinity and Siskiyou counties, though Nevada county shows a yield from this source of \$124,439. Trinity county produced \$233,093 and Siskiyou \$173,337 from hydraulic mines. Placer county leads all others in drift mining, its output having been \$331,002 from this source. Sacramento county comes next with \$213,867. Sierra, Butte and Plumas counties have been eclipsed in this respect by Sacramento, where little or no drift mining was carried on until recent years. The operations in the Blue Ravine section, above Folsom, have brought about this result. The largest drift mining operations, however, are still carried on in Placer county. The quartz mines, however, continue to be the main source of the California gold supply, the sum of \$12,247,892 out of \$16,300,653 having come from quartz mines in 1903. This shows that fully 75% of the California gold comes from the quartz properties, the other 25% being from hydraulic, drift and surface placer mines. The largest amount of quartz came in 1903 from Nevada county, followed in relative rank by the counties of Tuolumne, Calaveras, Amador and Kern, all of which show a yield in excess of \$1,000,000, Nevada county alone producing over \$2,000,000.

#### Amador County.

(Special Correspondence).—The drift being extended southeasterly from the Lincoln shaft toward the Wildman workings is in a fissure in which the gouge and stringers of quartz and calcite, characteristic of the proximity of an ore body in this region, are making their appearance. The material being passed through is showing low-grade values and are stated to be improving. This level is nearly 600 feet below the lowest level of the Wildman. In the latter mine on the lowest level, the 1400, drifting is progressing both north and south and good ore is being developed in both directions and the mills will soon be running to their full capacity. If these new developments continue to show improvement, it is the intention of the company to continue the Emerson vertical shaft, now down 650 feet, to 4000 feet or more and to equip the property with steel head frame, heavy hoisting machinery and larger milling facilities. The Emerson shaft is one of the best constructed and equipped shafts in the West, and through it a large tonnage of ore can be handled when connection has been made with the levels below the 1200 of the Wildman. The property includes the Wildman, Hector (Mahoney) and Lincoln claims, beside a large area of property lying on the hanging wall side and held originally under agricultural patent, so the extralateral right is secured. In recent years the career of this property has been handicapped by being obliged to work through small inclined shafts, sunk in the fissure, and the heavy, swelling ground has been a source of large and constant expense in keeping the ground open. With the extensive improvements contemplated it will make it possible to work a grade of ore considerably lower than at any time in the past history of the mine, excepting possibly the period during which open-cut work was the principal method of mining the ore. Fortunately the mine makes comparatively little water, although the amount of ground open is very large—many thousands of feet of shaft, level and stope. The ventilation will be vastly improved when connection is made between the main workings and the drift from the Lincoln shaft. John Ross, Jr., is manager, at Sutter Creek.

Sutter Creek, Jan. 23.

(Special Correspondence).—It has been decided that the railroad from Ione to the vicinity of Jackson and Sutter Creek shall be continued to the timber belt of Amador county, and shall be a standard gauge steam road, instead of electric. It will aid greatly in the development of this county, as heretofore a 12 to 13-mile up-hill haul has been necessary to bring in all mining supplies.

Sutter Creek, Jan. 25.

The twenty stamps from the Baliol mine have been put up at the South Eureka mine at Sutter Creek by B. B. Haven, superintendent, giving forty stamps in all.

#### Calaveras County.

The Voinich M. Co. has bought the 40-stamp mill of the Amador Queen mine, near Middle Bar, in Amador county, and will put it up at the Voinich mine at Bear mountain, 5 miles west of Angels Camp.

#### Fresno County.

The Copper King mine at Letcher, on Dog creek, 27 miles from Fresno, is being reopened by Chas. Leavitt, after being closed for two years pending litigation. The mine was opened on a schistose vein 100 feet wide, all mineralized, but with a pay streak 2 feet to 20 feet carrying carbonate, oxide and sulphide ores. Mine was operated by electric power generated from steam made by crude oil. The main shaft is 450 feet deep.

#### Inyo County.

The mill of the Southern Belle M. Co., near Laws, has been completed and given a trial run by Superintendent A. E. Vandercrook.

#### Kern County.

The electric plant of the Kern River Co. at Kernville has been completed. In anticipation of diverting the river into the power canal, Huntington and others of Los Angeles located placer claims along the river, which will now be worked. J. Wingfield found good dirt near Isabella.

#### Los Angeles County.

(Special Correspondence).—The Lowell & California M. Co. are working the Big Horn mine at the headwaters of the San Gabriel river, west of Palmdale. This is a low-grade proposition with a vein 50 feet wide which the superintendent, F. C. Fenner, claims to be working for less than \$2 per ton, using a modification of the caving method in mining. The fact that the vein lies at the low angle of 23° from the horizontal renders the cheap handling of this mine unusually difficult where so little timber is employed. The vein is developed by several tunnels. The company owns 500 acres of mineral land in the group with abundance of water for milling. The mill of ten stamps is being enlarged.

Los Angeles, Jan. 21.

The Reward M. Co. of New York is putting up a 75-stamp mill on its property between Lang and Rusk, in Agua Dulce canyon, where there is a large body of conglomerate ore.—H. S. Farnsworth of Los Angeles is drilling for water near Newhall, preparatory to working his placer ground.

#### Nevada County.

G. W. Root and H. Reher have struck the grave channel in the Auriferous on Randolph flat, near Nevada City, after running a 600-foot tunnel and a 45-foot up-raise.—At the Spanish Ridge mine, 6 miles above Washington, E. B. Miller has put in ten more stamps, giving twenty in all.

At the Idaho-Maryland the shaft has been pumped out below the 375-foot level and new timbers put in.—C. C. Weisenburger is putting in a new washing plant at the Banner gravel mine, near Nevada City.—It is reported that the Pine Hill mine, near Auburn, may be reopened by J. A. Robles.—The Yuba mine, at Maybert, is stoping ore from the upper levels.

#### Placer County.

At the Paragon drift mine at Bath, W. Rea is operating everything by water power at a great saving.

#### San Diego County.

Many new gem discoveries were made in southern California during 1904. They included blue and white topaz, weighing more than a pound apiece, which as crystals equal those of Siberia; beryls from 3 to 6 inches long and 1 or more inches in diameter, varying in color from pale green to a deep sea green tint; crystals of rose-colored heryl (a very rare variety), found at Mesa Grande and Pala; epidote in crystals only 1 inch long and 1/2 inch in diameter, but transparent; red, green and yellow tourmalines, found in abundance at Mesa Grande and Pala.

#### Trinity County.

The Lappin G. M. Co., working the Lappin mine at Deadwood, has put in a 5-stamp mill and will run a lower tunnel 900 feet to open up ore and drain the mine.

### COLORADO.

(Special Correspondence).—Suits aggregating \$250,000 have been brought in the district court against fifty of the prominent operators and citizens of the Cripple Creek district by the Western Federation of Miners. These suits are the outcome of the partial wrecking of the union stores in the district on June 6 and August 20, 1904. A deed for the union hall in Cripple Creek was placed on file a few days ago transferring the property of the Western Federation to the president of the Federation. This deed was made out several months ago, but was only recently filed for record. The deed recites that the union are unable to hold meetings in their hall in peace on account of the conditions existing in the district. The charter of the union was also surrendered.

Denver, Jan. 23.

#### Boulder County.

The Blackbird tunnel, at Sunshine, has been driven 315 feet by P. J. Collins.

#### Clear Creek County.

Estimates are being called for by the Yankee Con. M., M. & T. Co., at Yankee, for the equipment of the Lombard shaft with a 125 H. P. boiler, a hoisting plant strong enough to hoist two and a half tons at a rate of 600 feet per minute, an air compressor, etc. As soon as the next level is reached and driven, the Lombard mill will be enlarged to double its capacity. An aerial tramway will be built to connect the mines with the mill. H. I. Seeman is president and manager.

#### Gilpin County.

The Park tunnel of the Black Hills & Denver M. Co. in Boulder park is being retimbered and the company may put in an air compressor.—F. Augustus of Rollinsville has interested Iowa people in erecting a 10-stamp custom and concentrating plant near Rollinsville.—The sampling works of the Independent S. & R. Co. at Black Hawk, D. Allen manager, will buy a large rock crusher and rolls.—At the Lynne shaft of the Eldorado M. Co. at Russell Gulch levels are being driven at the 110-foot level. Sinking will be resumed from the 115-foot level. S. T. Harris is manager.—Manager Kirk of the Caseltine mine, near Central City, is retimbering the shaft and putting in machinery. The shaft will be sunk 300 feet.

F. Augustus, manager of the Mountain Monarch M. Co., operating in Gambell gulch, near Rollinsville, has raised capital in Iowa for a 10-stamp and concentrating custom mill to be erected on South Boulder creek.—J. H. White of Colorado Springs is unwatering the Victoria group at Gilpin, for Colorado Springs and Eastern parties who wish to examine the property. The main shaft is down 150 feet, with about 500 feet of level

work performed and the upper workings have produced considerable ores.—A 20-foot vein of medium-grade ore, which will make a first-class milling proposition, values running up to over \$15 per ton, has been opened up on the Hamilton group. It is the intention of the lessees to build a mill in the spring.—The Gold Dirt M. Co. will let a contract for a new 100-ton mill in Gambell gulch.

#### Gunnison County.

The Cripple Creek Gold Temple M. Co., which owns the Rocky Point and Lookout claims, on Shoop Mt., near Crystal, has given a five years' lease and bond for \$1,000,000 to J. Hirschfeld & Co. of Philadelphia, Pa., who intend to erect a mill of 150 tons capacity and build a 3-mile tramway from mine to the mill. The tunnel has been driven 1000 feet and the shaft sunk 700 feet.

#### Ouray County.

Work has been resumed on the Yale-Brown tunnel, near Red mountain, with C. M. Collins as superintendent. The property consists of thirty-four claims. The work consists of driving a tunnel, with the ultimate intention of extending it several thousand feet and developing Mineral and Porphyry basins. The tunnel is in about 100 feet.

At the San Pedro tunnel, near Ouray, being run by Terry & Trench of New York, the cost of which will probably reach \$125,000, the contractors are installing heavy machinery.—The excavation for the additional ten stamps at the Treasury tunnel is completed and the foundation ready to put in. The machinery will likely be delayed some time on account of the unsettled condition of the weather. The machinery already installed is running satisfactorily and the work on the big tunnel is going ahead.

#### San Juan County.

The Missouri Fred G. M. & M. Co., working at Middle mountain, 2 1/2 miles from Boulder, has closed down for the winter, but will resume work in the spring, making extensive improvements. The president is W. Ellsworth; general manager and secretary, F. J. Fraley; treasurer, C. B. Henney; superintendent, J. J. Rico, at Ignacio.

The annual meeting of the Mines Securities Corporation, held in New York, elected T. E. Leeds president, T. J. Hurley managing director, F. E. Pinto, Jr. vice-president, and T. J. Tilney secretary and treasurer. Mill No. 1 on corporation's Ruby Basin mines at Silverton, Colo., was started commercially on Dec. 1. Negotiations are in progress to erect on the Natalie mine next spring mill No. 2 of four times the capacity of the present plant.

#### Teller County.

The Isabella M. Co. at Cripple Creek has decided to sink the shaft on the Empire State an additional 500 feet to 1350 feet.—A sinker pump is being installed on the Nugget claim, owned by the Legal M. Co., in order to handle the increased flow of water. The shaft has reached a depth of 200 feet.—A contract has been let by the company leasing on the Mary Nevins to sink the shaft an additional 200 feet, which will send it to a depth of 325 feet.

### IDAHO.

#### Blaine County.

The Black Pearl M. Co. at Pearl have sunk a double-compartment shaft 415 feet and have run 1700 feet of tunnel. An air compressor and electric motor are being put in to operate the hoist, pump and drills. The shaft is to be sunk to a depth of 1000 feet. The company have bought the Lucky Ridge group and will sink a 390-foot shaft before drifting is started. R. B. Anderson is manager. E. E. Rodgers of Chicago is president.

#### Elmore County.

Spear's American Exchange is working the Basil mine, 20 miles north of Pine, with six men in the tunnel, which is in 140 feet. M. H. Jacobs is consulting engineer.

#### Idaho County.

The Sunnyside mill, in Thunder Mountain district, has closed after a trial run on 180 tons of low-grade ore. The superintendent, E. L. Ahcott, says the saving was satisfactory. The ore was crushed to 20-mesh. The tram, which has a cable 7345 feet long, made trouble at first through the method of attaching the buckets, and several of them broke loose with disastrous results. Modified grips to connect the buckets to the cable are being put in. The rock crusher at the mill, driven by power afforded by the descending ore on the tram, proved too small for handling the large pieces of ore coming from the stopes, and it has been decided to take in another crusher. Development in the upper works has stopped. The Burr tunnel is being driven to develop the ore blanket deeper. It will catch the lode by a raise of 175 feet. The tunnel is in 1650 feet and should be finished with 200 feet more driving by June 1.

#### Kootenai County.

It is reported that a stamp mill and cyanide plant will be put on the Farmer Jones mine, 8 miles from Priest river.

#### Nez Perces County.

The Hillside M. & M. Co. at Lewiston elected J. W. Killinger president and general manager, C. A. Varney secretary and E. F. Gordon superintendent. The company will build a flume, put in a motor and a sawmill in the main tunnel at Big creek.

#### Shoshone County.

The Oom Paul M. Co. will sink 300 feet on the vein at its property on French gulch, near Burke, and will put in an electric hoist and pump to be run with power from Spokane.—The Morning M. Co., at Mullan, has driven the working and drainage tunnel over 6000 feet.

### MONTANA.

Regarding mineral production in 1903, the United States reports credit Montana with producing 272,555,854 pounds of copper. The production was hampered by the continuance of legislation in Butte, which produces the hulk of the product. The Amalgamated Copper Co.

controls the Anaconda, Colorado, Parrott, Butte & Boston, Boston & Montana, and Washoe properties, the ores of the Anaconda, Colorado and Parrott companies being reduced at the Washoe smelter. The Butte Reduction Works treat the ores from the mines owned by W. A. Clark, and the United Copper Co. smelts the ores of the Minnie Healey, Corra-Rock Island and Rarus mines. The Pittsburg & Montana M. Co. has been developing its mines and has erected a smelting plant. The Speculator mine ships its ores to the smelters of the district. None of the companies of the district publish annual reports, so that statistics relating to the yield of the ores, to costs, or to financial results are not available. Statements are annually filed with the tax commissioner of Montana, which cover a fiscal year, but since they do not embrace figures as to the output of copper, silver and gold, they permit only of approximations as to the capacity of the district. Copper is also found in the counties of Beaverhead, Cascade, Deer Lodge, Granite, Jefferson, Madison, Meagher, Lewis and Clark, Park, Silver Bow and Teton, the ores being mainly sulphides, usually associated with diorites intrusive in Cambrian quartzites.

#### Granite County.

The Gold Reef M. Co., near Phillipsburg, has been closed by Superintendent J. H. Price until spring.

#### Lewis and Clark County.

The Montana Standard M. Co., near Marysville, opening up the veins on the east end of Cruse hill, expects to run a 3000-foot tunnel to develop a vein recently struck.

The Whitlatch M. Co., operating the Whitlatch-Union mines at Unionville, 4 miles from Helena, is sinking the main double-compartment shaft and may erect a milling plant. F. L. Sizer of Helena is manager.

#### Silver Bow County.

The Montana Zinc Co. is building a mill at Walkerville to extract the zinc from the ore from the Alice mine. It has purchased the Emma mine for \$100,000 to be worked in connection with the Alice, and will repair the shaft, put in new machinery and work it for zinc. These mines were formerly worked for gold and silver. The process of zinc extraction is very largely the invention of C. B. Wisner of New York, the president of the company.—The Reins Copper Co. is shipping ore from the Combination mine at Meaderville in the Summit Valley district. The Jeanesville pump at the new station at the 800-foot level is capable of pumping 700 gallons per minute to the surface. Ore bins have been constructed near the shaft, and are heated with steam to prevent the ore freezing. The ore is treated in the Washoe smelter at Anaconda. E. J. Trerise is superintendent.

#### Ravalli County.

At the Verdi mine, 16 miles northeast of Hamilton, good copper ore has been found by O. E. Smith. J. C. Carter is superintendent and will develop the property extensively.

### NEVADA.

#### Esmeralda County.

The Western Ore Purchasing Co. of Reno will build a 700-ton sampling works at Goldfield.

#### Humboldt County.

The Sheha G. & S. M. Co. say that they have 4000 feet of track in their workings at Unionville. The new tunnel is in 1100 feet. They have built a dam to increase the water supply, and put in a 5000-foot pipe line, air compressor and a drill.

#### Lincoln County.

C. G. Austin of Los Angeles, Cal., has bonded the Hare & Hunsaker property at Eldorado, and will drive a 650-foot crosscut tunnel.—The Duplex M. & M. Co. at Searchlight, F. P. Swindler manager, will sink a 500-foot shaft and put in a 40 H. P. hoist.—The new 10-stamp mill of the Quartette has been started while the old batteries are being repaired.

#### Nye County.

The Tonopah Sun says that freighters between Tonopah and Goldfield will charge 1 cent a pound for all general merchandise and 2 cents a pound on household goods. The advance is from \$15 to \$20 a ton on the first kind of goods and an increase of from \$15 to \$25 on those of the second class. The reason for making the advance is not claimed to be arbitrary on the part of the freighters. They have, within the past few weeks, been compelled to meet advances which would so reduce their profit that they would be able to make but a bare existence. The railroad company has raised the freight on hay from Sodaville \$10 a ton, and has issued an order that hereafter every two cars of hay will have to be accompanied by a man. This is for the purpose of keeping the hay from catching fire. When the trip is made from Sodaville without stopping, the wages of a watchman are \$4 per diem. Sometimes, however, the cars are sidetracked between the two towns, and the sum paid to the man in the employ of the shipper takes whatever profit there may be in the hay. One company asserts that it has two cars of hay that are sidetracked on the desert, and that the cars have been standing on the siding for two weeks. The producers have doubled the price of horse feed within the last thirty days.—The Manhattan-Tonopah M. Co. of New Jersey is developing the five claims, and will install a first-class hoisting plant.

The Little Frankie G. M. & M. Co. has been formed at Ogden to work the Little Frankie, Irene, Gold Standard and the United Gold by J. F. Smith, president. E. A. Smith, secretary and treasurer, and W. Copernall, managing director.

#### White Pine County.

The White Pine Copper Co. is experimenting with the ores of the Ruth, Last Hope and Columbia at Ely. They will put in a mill and concentrating plant and perhaps reduction furnaces. The copper occurs as sulphide in a kaolinized mass carrying gold. M. L. Requa, 100 Front St., San Francisco, Cal., is interested.

### OREGON.

#### Grant County.

G. Walker is manager of the Dredge Co., working the placer ground on John Day river and Canyon creek, above the junction.

F. McDonald of Prairie City has sold one-half of the New Year's Gift to T. H. Murphy of Greenhorn.—The new mill of the Dixie mine at Prairie City has been temporarily shut down by Z. Houser because of cold weather.—The Crane Flat placers, near Granite, are to be worked by the Western M. & D. Co. The pond to float the dredger has been dug and the machinery has been delivered, but will not be set up till spring. A. Burch of Seattle, Wash., has charge.

#### Jackson County.

The Siskiyou M. & D. Co. has been formed at Ashland to develop and operate placer and quartz mines in placer county, Oregon, and Siskiyou county, Cal., by T. J. Nolton, Wm. Hulen, A. H. Findley, J. W. Potter.

#### Wallowa County.

The Tenderfoot G. M. Co. will put up a 20-stamp mill at the mines on the upper Imnaha river, 62 miles from Elgin; also an aerial tramway from mine to mill. Dr. Tripp of Sioux Falls, S. D., is president.

### SOUTH DAKOTA.

T. Gregory, State Mine Inspector of South Dakota, in his annual report states that there are 3500 wage earners on the payroll of South Dakota mining companies, employed as miners, helpers and timbering crews, mill men and mechanics. The average daily pay of the miner is \$3.50, helpers \$3 and shovelers and mill hands \$2.50. The compensation of skilled mechanics about the mines is considerably higher. Generally the length of the day is ten hours where mining is regularly conducted, although in the sinking of shafts and the running of other new work, where conditions are trying and where the most rapid headway possible is desired, three shifts of eight hours each are sometimes employed. The bodily welfare of employees is given commendable attention by the management of every important mine in the State; all reasonable pains are taken to guard against accidents that might produce loss of life and injury; rooms are in most instances provided where employees going on or off work may change raiment and bathe in comfort during severe weather, and, where necessary to mining companies employing any considerable number of men, boarding and lodging houses have been built by the companies at points convenient to work. Rules of sanitation are carefully observed, and adequate ventilation is afforded in the remote recesses of the mines to keep the atmosphere pure when men are working, while in some of the mills, where dust would otherwise be objectionable if not a dangerous element, dust collectors used on fans have been introduced to keep the air free of the floating particles.

The following shows the daily tonnage of the various gold reduction plants in the State which have been in use all or part of the year: Alexander Maitland, 120; Clover Leaf, 240; Dakota, 120; Golden Reward (cyanide plant), 200; Hidden Fortune, 120; Homestake, 4000; Horseshoe, 300; Imperial, 125; Lundberg, Dorr & Wilson, 100; Spearfish, 250; Wasp No. 2, 125; Black Eagle, 20; Clara Belle, 20; Cochran, 20; Columbus Con., 75; Extreme, 40; Golden Crest, 40; Rossiter, 50.

The following summary from Black Hills mines shows the field operations of the various companies. Alder Creek G. M. Co. owns 65 acres on Yellow creek; suspended operations a year ago owing to internal complications which are now being adjusted, with reasonable prospects of a resumption at the 65-ton cyanide mill. Branch Mint M. Co. is building mill of 120 stamps and 3 miles of narrow gauge railroad in Bear Butte district. Clara Belle M. Co. has introduced new machinery and resumed work late this year in its Tremaine mill. Clover Leaf G. M. Co. is operating 60 stamps and adding \$200,000 worth of new machinery. The shaft is being deepened from the 700 to 1,000-foot level, and the developments of the year have been very favorable. Ventilation is good, produced by connection with open cut and circulating water. Cochran mine, owned by Jas. Cochran, operated a small mill part of the summer. Columbus Con. M. Co. suspended mill early in the year, and is developing with crosscut drifts at 500 feet in depth. Dakota M. & M. Co. mine and mill running full capacity since beginning of the year. New shaft started and equipped with modern machinery, intended to explore lower ore horizon. Deadwood-Standard G. M. Co.: Extensive prospecting is under way with drills in quest of higher grade ore; meanwhile the mill is suspended. Extreme G. M. Co. built a 10-stamp mill near Custer early in the year and has operated it several months. Gilt Edge Maid M. Co.: A new mill, to be run by electric power, has been finished and is ready for the initial run. Golden Reward M. Co. operating only its cyanide plant at Deadwood, as the smelter at Deadwood has not resumed since it was closed in March, 1903. Ore is taken altogether from the northerly mines of the company's group. Golden Crest M. Co. has devoted the last 10 months to development of the property. Hidden Fortune G. M. Co.: New mill has been running greater part of the year, with gradual increasing capacity. The ore is taken from the flat, siliceous formation and from the tunnel in the vertical. Homestake M. Co. has added 100 stamps to the Amicus mill during the period, giving the company a total of 1,000 stamps, and the monthly output of the mines greater than ever before. The costly improvements that have been under way about the property for over seven years have been practically completed, the producing ability of the mine is greatly enhanced, valuable and permanent improvements are the result, and the company is fortified for an indefinite period of successful operation. The deepest shafts are 1,250 feet deep, from the bottom of which development is under way. At Horseshoe M. Co. nearly all the stamps in the 120-stamp mill are in service. Important improvements have been added to the mining and milling facilities. Imperial G. M. and M. Co. has acquired the McGovern group and Greenough group. Cyanide mill at Deadwood is in continuous operation. Lexington Hill G. M. Co. is driving a tunnel to connect the mine and

mill directly. Lundberg, Dorr & Wilson are owners of the Buxton and Big Bonanza mines and a modern cyanide plant, which has been in continuous commission since early in the year. The plant is driven electrically. Ore is delivered by railroad and aerial tramway. The Alexander Maitland has attained success at its 40-stamp, wet crushing cyanide plant, and is also shipping to outside smelters. It has added largely to its mining and milling machinery, including a large compressor, which gives increased pressure and consequently increased ventilation. The Portland & Clinton M. Co. are mining in the old workings and making occasional shipments to the cyanide plant of Lundberg, Dorr & Wilson, and to outside smelters. The Wasp No. 2 M. Co. is putting in new machinery, consisting of additional crusher and rolls, to avoid loss of time from closing down when repairs are necessary. An improved system of mining is being inaugurated at the mine, which will make possible still greater improvement.

#### Custer County.

(Special Correspondence).—At the Clara Belle M. Co., 1½ mile from Oreville, on the Burlington R.R., 7 miles from Custer, the shaft is down 240 feet, and they are drifting in a vein of rich ore from 8 to 10 feet wide. There is a new 60 H. P. boiler and steam hoist and pump and a mill house with 2-stamp Tremaine mill, now running one shift, but will soon start on double shift. The company will put in a 10-stamp mill with cyanide tanks for treating the tailings.

Custer, Jan. 22.

#### Lawrence County.

The 60-stamp mill of the Clover Leaf mine, near Perry, is being repaired and improved and will start again in March. O. B. Amsden is superintendent.—The 500-ton smelter of the Golden Reward M. & M. Co., at Deadwood, is to be blown in soon.—W. E. Hahn of Deadwood has charge of development work on the Anaconda, on Elk creek, east of Perry.—The Imperial G. M. & M. Co. will add crushing machinery and leaching tanks, so as to increase the capacity to 300 tons per day, 200 tons being present maximum capacity. J. T. Milliken of Deadwood is mill superintendent and R. S. Jamison of Deadwood general manager.—The Aurizone M. Co., N. H. Conger of Custer secretary, contemplates building a 100-ton cyanide plant to treat the ores from its mines, 1½ mile north of Galena.—The Victoria G. M. & M. Co. proposes to build a 200-ton cyanide plant at Maurice. G. S. Jackson of Deadwood is manager.—A 200-foot shaft is to be sunk on the Ruby, in the Bare Butte mining district, 1 mile from Galena. J. Conzett of Deadwood has charge.—J. T. Harrington of Deadwood, owner of the Fairview mine and 10-stamp mill near Mystic, intends to build an aerial tramway from mine to mill.—On Iron creek, 3 miles northwest of the Spearfish mine, at Ragged Top, W. H. Disney of Terry proposes to install a hoisting plant for the Iron Creek mine. C. A. Carlson of Terry is mine superintendent.

#### Pennington County.

J. B. Taylor of Rochford, president of the Burlington Co., working at Friday gulch, intends to put in a hoist. The shaft is 150 feet deep.—A. R. Arundel of Hill City is building a mill for the Gopher mine.

### WASHINGTON.

#### Okanogan County.

The Palmer Mt. Tunnel Co., at Loomis, will put in an electric plant on Toats Coula creek and put in a large air compressor plant to aid in driving the tunnel 4000 feet farther.—The Grand View M. Co. will put a 20-stamp mill on its property on Mt. Chopaca. Machine drills are to be put into the mine. The mill is to be run by electricity generated by a plant to be built by the company at the mine.—The Mineral Hill M. Co., near Conconully, will put in an electric plant on Salmon creek to furnish power for the machine drills driving the tunnel and for an electric railway to connect the mine with the boat line on the Okanogan river.

#### Spokane County.

The Roselle M. Co. is producing tungsten at Deer Trail, in the Cedar Canyon camp, northwest of Spokane. W. S. Thyng says that the lode is 20 inches between walls, with a quartz filling, and 200 feet of development has been done. He expects to put up a concentrator in the spring.

### FOREIGN.

#### AUSTRALIA.

##### New South Wales

The gold yield of New South Wales for December, 1904, was 40,414 ounces, valued at £121,373, as compared with 8000 ounces, valued at £30,488 in December, 1903. The yield for the whole year was 324,996 ounces, valued at £1,146,109, as compared with 295,778 ounces, valued at £1,080,029 in 1903.

### BRITISH COLUMBIA.

#### Atlin District.

This district is devoted almost entirely to gravel mining, producing over \$600,000 in 1904. The latest available reports show the following companies to be operating: The British-American Dredging Co., O. T. Switzer, general manager, at Pine creek; the Pine Creek Power Co., L. H. Griffith, manager, and M. W. Loveridge, hydraulic superintendent; the Willow Creek M. Co., F. H. Brackett, manager, at Pine creek; the Eastern Hydraulic M. Co., on south side of Pine creek, above Discovery, J. M. Deeks, manager; the North Columbia G. M. Co., J. M. Ruffner, manager, at Pine creek. Regarding the work of these during 1904 the British Columbia Mining Record reports that the Willow Creek M. Co. proposes to add to their plant and increase the force. The Pine Creek Power Co. has worked a large area of the benches on the south side of Pine creek, below Discovery. Dynamite was used successfully to loosen the gravel. The company let a contract for the construction of several hundred feet of ditch to replace a flume that previously was the cause of much trouble. The North Columbia M. Co., purchasers of the Leeks &

Stewardsyke leases and quartz properties in the district, confined operations this year to opening up a new pit on the north bank of Pine creek, using the water from the Weeks ditch to loosen the dirt. Considering the amount of preliminary work to be done before commencing active operations, the result of the company's work is highly satisfactory. The company owns a large area of ground known to contain two distinct pay streaks or channels and with further development the gold recovery per year should yield large profits. The company also prospected the Stovendyko, with intent to work next season. Spruce creek benches were worked by individuals. The Con. Spruce Creek Placers Co., C. B. Gaddis, manager; H. Haslitt, hydraulic superintendent, opened and worked one pit on lower Spruce creek, reaching the Spruce creek pay channel with encouraging results. Other companies on Spruce creek are the Gladstone, S. O. Wheelock, manager; the Columbia Hydraulic M. Co., E. F. Meisner, manager, and the Blue Canyon, R. A. Jackson, manager. Ruby creek was successfully prospected preparatory to considerable work next summer. The Bull Creek Hydraulic Syndicate carried on extensive prospecting on Bull creek, a tributary of Dixie creek. On upper Spruce creek, O. F. Switzer is manager for a company building a dredger similar to the one operated by the British-American Co. on Gold Run. On Boulder creek, Grant & Black are working some of the ground of La Societe Miniere de la Columbie Britannique, of which H. Maluin has been local manager. On Birch creek, A. B. Williams is manager of the Atlin Lake Co. The McKee Creek Con., the purchasers of the holdings and plant of the Nimrod Syndicate in Atlin district this year, hydraulicked the benches of McKee creek. This company is under the management of the Samslow Bros., who report a most successful season's work, which yielded a return of some \$70,000, the largest return yet obtained on McKee creek. Other companies that have been interested here are: The Atlin M. Co., R. D. Featherstonhaugh, manager, and M. Brophy, hydraulic superintendent; the McKee Con., C. Christopher, manager.

#### Boundary District.

Regarding the Nickel Plate mine on Nickel Plate mountain, 5 miles by trail from Hedley, the Hedley Gazette says that the mine is operated by the Yale M. Co. and the rest of the work, including ore haulage, flume, stamp mill, cyanide plant and power house, is done under the name of the Daly Reduction Co. M. K. Rodgers is general manager of both companies. G. P. Jones is superintendent of the mines; W. P. Rodgers, chief engineer of construction, surface and underground; A. H. Brown, superintendent of stamp mill and cyanide plant; J. C. R. Cootes, superintendent of power and electric plants; E. R. Kelzer, draftsman; G. P. Lyon, foreman of surface gang. The ore body may be described as a mineralized zone of sedimentaries crushed between bodies of andesite. The value is found in the auriferous mispickel. The development has been almost entirely by tunnel. The main or lower tunnel has been driven about 1000 feet and exploratory drifts to ascertain the extent and value of the ore body have been run in different directions, both on this and the upper tunnel. The first of these drifts was along a fault plane to a point underneath the glory hole, and an upraise was made of 150 feet, connecting the glory hole with the main tunnel by two chutes, the extra one being available in case of accident to the other. The mill is supplied with ore from the glory hole, 15,000 tons having been taken out and carried 18,000 feet by tram to the mill at Hedley. For the first half of this an altitude of 4700 feet had to be overcome, and on the upper half less than 400 feet. The lower half is traversed by a gravity tram and the upper half, with its flatter grade, by an electric tramway, 9000 feet long, built on a maximum grade of 5% and a minimum of 2%. This is equipped with twenty-two cars of 2 tons capacity each, and drawn by a 15,000-pound electric motor, to which will soon be added another motor of 20,000 pounds. The electric current for the trolley is generated at the power house by a generator driven by water from the penstock and transmitted as a 2200-volt alternating current to the head of the gravity tram, where it is transformed to a 550-volt direct current. No power is required to haul the ore from the mine on the electric portion, which, being all down grade, enables the ore trains to run of themselves, controlled by the brakes, power only being required to start the load and pull back the empty train. The ore is brought from the tippie by a gravity tram to the ore bin. From the bin it passes through a chute onto a 10-foot grizzly with 1-inch spaces between the bars. After the fines have been taken out by the grizzly, the coarser rock passes into the 10x20 Blake crusher. This crushes to 1½ inch, and after passing over another grizzly the oversize goes to a 6x20 crusher of similar pattern. From this it drops onto a belt conveyor which carries it over the large ore bin when it drops onto another belt conveyor running at right angles. This is used to distribute the ore along the entire length of the 2000-ton storage bin. The mill has forty stamps, each weighing 1050 pounds, with 7-inch drop, 92 per minute, 6-inch discharge through 20-mesh screen; amalgamating plates have grade of 1½ inch per foot; the concentrates are saved on sixteen Frue vanners, eight more are to be added, the tailings pulp being leached and cyanided; electricity, generated by water power, is used throughout.

The Montreal & Boston Copper Co. are considering equipping their smelter at Boundary Falls with electric power. There are three furnaces, 40x176 inches at the tuyeres, of 400 tons daily capacity, with automatic samplers, crushers, rolls, belt conveyors and a 250-light dynamo. A. I. Goodall is smelter superintendent.

#### Carlboo District.

(Special Correspondence).—A scheelite mine has been discovered near Barkerville, containing 10% and upwards of scheelite showing 78% of tungstic acid.

Barkerville, Jan. 20.

J. McRae is ready for piping his hydraulic property at Quesnel Forks.

#### Kootenay District.

The Lardeau Valley Mines, Ltd., propose to put up

milling and concentrating works at the mouth of Tenderfoot creek, to work the mines of the John L. Liza and Handy veins. The Hendy is 1½ miles south of Gerard. W. N. Brayton of Spokane, Wash., is president and J. Mackenzie secretary.

#### Lardeau District.

The Eva mill, near Camborne, has been started for the first time since operations were suspended last August owing to the tram and mine buildings being burned out by forest fires. All the machinery has been overhauled. The tram which has been rebuilt has started. Construction of the tram, which will connect the upper workings with the main tram, is progressing well, all the towers being in position. When this tram is completed, ore for mill treatment will be available from all parts of the mine.

#### Nelson District.

P. Clark of Spokane has bonded the Queen mine at Salmo from J. A. Turner, W. Waldie and M. Scully and the Kootenay Belle from Bennett & Billings of Salmo. The B. C. Standard M. Co. of Nelson will put a crusher at the Hunter V to break the ore before sending it over the tram. The main double-rope aerial tramway to the railway is 13,000 feet long.

#### Rossland District.

The metallic output from the Granby smelter for 1904, estimating the output for December, was: Gold, 50,694 ounces, at \$20, \$1,013,880; silver, 217,472 ounces, at 57 cents, \$123,949; copper, 17,843,399 pounds, at 12.8 cents, \$2,283,955; total, \$3,421,784. The totals are 401,921 tons for 1903, and 596,252 for 1904. Of this latter amount, the company's own mines at Phoenix furnished 549,703 tons, leaving a balance of 46,540 tons that came from outside mines in the Boundary, Republic, Ymir, Rossland and Orient and other camps. The six furnaces, 44x160 inches, have a nominal daily capacity of 2100 tons; they treated an average of over 1600 tons daily. The ore is practically self-fluxing, and is charged as mined without milling or concentration. The product of the first fusion is a 60% matte, which is blown up by converters to 99% blister copper. There is a 20-ton reverberatory tilting furnace. Slag is granulated.

The report of the Le Roi No. 2, Ltd., for the year ended Sept. 30, 1904, shows that as a result of the year's working, 23,020 tons of ore were shipped to the smelter and 10,331 to the concentrator. Of the former, 21,680 were from the Josie mine, and gave an average of \$24.80 per ton, as against \$20.69 for the previous year. The 23,020 tons shipped realized \$638,410, inclusive of an estimated amount of \$33,000 for ore in transit. The cost of mining, diamond drilling and general expenses in Rossland amounted to \$150,747, leaving a gross profit of \$217,663, but from this has to be deducted London expenses and \$60,529 written off for development and depreciation. The gross value recovered is \$3.15 per ton, of which \$2.02 was from the Wilfley tables and \$1.13 by oil. J. W. Astley is general superintendent.

#### MEXICO.

##### Chihuahua.

The new shaft on the Capazaya at Parral is down 310 feet.

The electric hoist has been started at the El Duque shaft of the San Nicolas M. Co.—The Sierra Madre is hoisting 350 tons of ore a week and is shipping. The pumps have been working continuously since started and the mine is sufficiently unwatered to allow drifting at the 600-foot level.

##### Durango.

The Guanacevi Tunnel Co., recently organized with a capital of \$5,000,000 gold, will commence work on the 10,000-foot tunnel they are to drive in the Guanacevi mining district. It is to be 8 feet high and 12 feet wide and will have a double tramway track for the entire length. The officers of the company are H. Losoya, president, at Guanacevi, and F. Griese, treasurer, at Parral.

At Mapimi the Compania Minera de Penoles in 1904 mined 160,841 tons of ore containing 22,771 tons of lead; 241,000 tons of ore were smelted with a net profit of \$2,303,990.44 Mexican. The shaft is now 2950 feet deep. In 1904, approximately 175,000 tons of ore were mined, assaying eighteen ounces silver per ton, 0.15 ounces of gold per ton and 15% to 16% lead; 240,000 tons of ore were smelted, one-quarter being siliceous fluxing ore, purchased principally from Parral. Nearly one-quarter of the ore mined is sulphide. The Huntington-Haberlein process is now in operation with a capacity of 300 tons daily. The Mapimi M. & S. Co., operating the America mine, and the San Juan M. Co., also operating at Mapimi, have both developed some ore during the year.

The Mining Journal reports the following mines in Mapimi as working on a regular scale: Ojuela, Socavon, Concepcion, Santa Rita, San Judas, all of the Sierra La Bufa district, and owned by the Penoles Mineral Co., S. A. Descubridora, Descubridora; owned by the Cia. Minera y Fundidora, Descubridora. La Reina, Santa Librada; owned by Miguel Torres & Co., C. Lerdo Dgo., and worked by the Penoles Mineral Co. The following have been working on a small scale: La America, Sierra La Bufa; owned by the Cia. La America, S. A., and worked by the Cia. Minera y Fundidora, Mapimi. San Juan, Sierra La Bufa; owned by the San Juan M. Co. Providencia, Talpa, Sierra La Bufa; owned by Pedro Moreno, Mapimi, Durango. Siderita, Descubridora; owned by the Siderita M. Co., S. A.

##### Guanajuato.

The Mining Journal says that the following mines in this district have been working on a regular scale: Sirena, owned by the Guanajuato Con. M. & M. Co.; Tunnel of San Francisco, owned by the El Cubo M. Co. (English); Peregrina, owned by the American Co.; El Cedro, owned by the El Cedro y Anexas, S. A.; El Pinguico, owned by Amado Delgado & Co.; Cata, owned by Guanajuato Reduction & Mines Co.; Jesus Maria & Villalino, owned by the executors of F. de P. Castenada; La Asuncion, owned by Atanasio Rocha. The following were worked on a small scale: Valenciana, owned by the Guanajuato R. & M. Co.; Penafiel, owned by Atanasio Rocha; Rayas & Mellado, owned by the Concordia

M. Co. The following metallurgical plants have been regularly worked during the month: Under the patio process—La Purisima, Cipreses and Dolores de Granaditas. Grinding pans—San Francisco de Pastita, owned by the Guanajuato Con. M. & M. Co. Concentration process—Machinery has been erected at the Peregrina mine, for the purpose of treating ores with cyanide of potassium. This machinery is worked by electric power.

##### Sinaloa.

Negociacion Minera de Guadalupe de los Reyes (Mazatlan) are working the Candelaria and Estaca y Descubridora at Cosala.—The thirty stamps of the Dulces Nombres, Canes, are crushing seventy tons daily from the Estaca, tailings from the Wilfleys being cyanided, giving from 50% to 70% extraction and costing \$7 to \$8 per ton.

A. Sanchez, H. E. Gaxiola, C. Vilderrain and E. Vasquez, owners of the Alianza and Morelos mines in the Badiraguato district, have decided to erect reduction works near the mines.

##### Sonora.

(Special Correspondence).—One-half the new concentrator of the Cananea Con. Copper Co. has been completed and is in operation. The capacity, when entirely finished, will be 1000 tons daily.—V. R. Parker has denounced 36 pertenencias in La Brisca district.—W. J. Powers, vice-president of the Calumet & Sonora M. Co., has gone East to purchase machinery.—The Cubao M. Co., G. H. McLean superintendent, at Arizpe, hopes to resume work in a short time. Cananea, Jan. 23.

It is reported that the La Chumata M. Co., working in Arispe district, 45 miles from Poza, will put in a fifty-ton mill. B. F. Scheffels is president and H. Baldwin secretary, at 159 La Salle St., Chicago, Ill.

#### NEW ZEALAND.

The gold output of New Zealand for December, 1904, was 28,531 ounces, valued at £112,017, as compared with 49,794 ounces, valued at £193,261 for the corresponding month of 1903. The total output for the year was 519,720 ounces, valued at £1,987,501, against 533,314 ounces, valued at £2,037,831 in 1903.

## Personal.

F. L. WHIPPLE is superintendent of the Federal Loan mine at Nevada City, Cal.

E. JENKS is superintendent of the Vesuvius mine, at Bohemia, Lane county, Or.

J. A. WARNER of Reno is at Virginia City, Nev., examining the Comstock mines.

F. GARRETSON is manager for the Garretson M. & S. Co., at Calera, Sonora, Mexico.

J. I. ORBISON, secretary of the Hawkeye M. & M. Co. of Nezperce, Idaho, is at Louisville, Ky.

J. D. ROBERTSON is superintendent of the Guadalupe mines, Villaldama, Nuevo Leon, Mexico.

C. G. DENNIS has been appointed superintendent of the Rawhide mine, Towle, Placer county, Cal.

ED. CHAMBERLAIN is superintendent for the Yaqui C. Co., Suaqui de Batuc, Santo Nino, Sonora, Mexico.

N. O. BAGGE of Los Angeles, Cal., is visiting his mines in the Almoloya district, Parral, Chihuahua, Mexico.

C. M. FUELLER, Denver, Colo., is in Atlantic City, Wyo., starting the 100-ton cyanide plant of the Dexter M. Co.

J. PARKS has been appointed superintendent of the Hawley-Gardner mine, on Quartz Hill, near Central City, Colo.

A. C. MORRISON has resigned as superintendent of the Rio Vista copper mine, near Fairplay, El Dorado county, Cal.

W. W. ELLIOTT has finished the construction of the Lucky Tiger mill at Sonora, Mexico, and will return to Prescott, Ariz.

A. S. HASKELL is superintending the building of the new plant of the Mountain C. Co., at Bull's Head Point, Contra Costa county, Cal.

J. CRONIN has been made general manager of the War Eagle and Center Star mines, at Rossland, B. C., succeeding E. B. Kirby.

G. H. ROBINSON, general manager of the Britannia copper mines on Howe sound, above Vancouver, B. C., is in Salt Lake City, Utah.

L. S. WOOD is at Denver, Colo., having resigned as manager of the Ashanti Gold Fields Corp., Ltd., Obuassi, Gold Coast Colony, West Africa.

J. C. CLANCY of Johannesburg, S. A., is making experiments at the Cripple Creek-Homestake mill on the Cripple Creek ores in Cripple Creek, Colo.

F. C. LINCOLN is manager of the Arizona G. & C. Co.'s properties at Saltillo, near Nogales, Santa Cruz county, Ariz., succeeding H. Vaughn, resigned.

C. R. DAVIS, superintendent of the Center Star and War Eagle mines at Rossland, B. C., has resigned to take the management of the Lancaster mines at Krugersdorp, South Africa.

JOHN M. BECKWITH, formerly manager of the Silver King (Ltd.) Co. of Calico, Cal., and now manager for the Nile Valley Co. in Egypt, is now in London on company business. He expects to return to the mines near Assouan in a few weeks, when extensive additions will be made to the hoisting and pumping equipment at the mines.

## Commercial Paragraphs.

THE Kilgore-Peteler Co. of Minneapolis, Minn., has absorbed the Kilgore Machine Co. and the Peteler Portable Railway Mfg. Co.

THE Redfield Drill Co., 1606 Blake St., Denver, Colo., recently shipped one of their hand power rock drills to the Moffat Lake & Reduction Co. at Gorham, Colo.

QUEEN & CO. of Philadelphia, makers of scientific appliances, have removed their instrument factory from Filbert street to the Cornelius building, 817-831 Cherry Street.

THE United Zinc & Chemical Co., whose establishment was recently destroyed by fire, are rebuilding and will continue business. Their office is 318 Dwight building, Kansas City, Mo.

THE Mine & Smelter Supply Co. of Denver, through their New York office, has received orders from the El Cobre mines for twenty-four Willey tables and six slimmers for their works at Santiago de Cuba.

THE Westinghouse Electric & Manufacturing Co., Pittsburgh, Pa., have opened an office at 429 Seventeenth street, Denver, Colo. Mr. L. M. Cargo, manager of the Salt Lake City branch of the Westinghouse Co., will have charge of the Denver branch.

THE Davenport Locomotive Works, Davenport, Ia., have spent \$30,000 in increasing their equipment. They have added a new power plant 80x160 feet, machine shop tools, generators, motors, etc. This expenditure is due to the increased business of the company. They recently shipped a locomotive to the Great Western Gold Co. at Logot, Shasta county, Cal. This locomotive is made to go into a 5-foot 2-inch tunnel. The Pacific coast representative of the Davenport Locomotive Works is J. C. Martin Jr., 117 New Montgomery street, San Francisco, Cal.

THE Pelton Water Wheel Co., 124 Main street, San Francisco, Cal., and of New York, report sales of a 700 H. P. Pelton wheel to the Grande Ronde Electric Co. of Oregon, to operate under 877 feet pressure, and a 450 H. P. Pelton wheel for the Nanaimo Electric Light & Heating Co. of British Columbia. The Silver Lake mines of Colorado have ordered a 600 H. P. Pelton wheel, to be direct coupled to a 400 H. P. Allis engine, to drive generators in the power plant. A 450 H. P. Pelton wheel unit is being made for the Government of Hawaii, and a 900 H. P. unit for the La Grande Water Storage Co. of Oregon.

## Books Received.

"Comparison of a Wet and Crucible-Fire Methods for Assay of Gold Telluride Ores" by W. F. Hillebrand and E. T. Allen, Bulletin 253 of the United States Geological Survey.

"Kittanniog Folio," Pennsylvania, No. 115 of the Geologic Atlases of the United States, published by the United States Geological Survey, deals with general geology of region, together with economic coal, oil and natural gas occurrences.

"The Stone Industry in 1903" is the latest of the series of Mineral Resources of the United States, issued by the United States Geological Survey. A review of figures shows an increasing production of crushed stone, but a slight decrease for the year in building stone. The report gives statistics on production and tests of stone from all of the States.

The difficulties of obtaining accurate information regarding mineral production is well exemplified upon comparing "The Mineral Resources of the United States for 1903," by D. T. Day, published by the United States Geological Survey, and "The Mineral Industry for 1903," as published by the Engineering and Mining Journal. The former states the total value of the mineral production during 1903 to have been \$1,419,721,569, while the latter gives the net value as \$1,474,275,125. The gold and silver production obtained from the mint reports are the same, but the base metals and non-metallic products, particularly coal, vary greatly. The "Mineral Industry" has considerable information regarding foreign production. It seems to be up to the standard set by the preceding eleven volumes.

## Trade Treatises.

Catalogue No. 9 of William R. Perrin & Co., Forty-sixth, Loomis and Bishop streets, Chicago, Ill., is devoted to pictures and descriptions of filter presses and filter press supplies. It will be sent to those interested upon request to either the Chicago or Denver office.

Catalogue No. 56 from the Whitman & Baroes Mfg. Co., West Pullman, Ill., is a fine example of a trade treatise, the illustrations and text elaborately portraying their extensive line of drill bits, chucks and cases, reamers, taps, wrenches and other tools. S. J. Cooger, 519 Mission St., San Francisco, Cal., is their Pacific coast representative.

## Obituary.

J. K. MACKENZIE of Chicago was murdered by Yaquis, near Hermosillo, Sonora, Mexico, on Jan. 19.

## Latest Market Reports.

SAN FRANCISCO, January 27, 1905.

### METALS.

SILVER.—Per oz., Troy: London, 28<sup>3</sup>/<sub>4</sub>d (standard ounce, 925 fine); New York, bar silver, 61<sup>1</sup>/<sub>2</sub>c, refined (1000 fine); San Francisco, 61<sup>1</sup>/<sub>2</sub>c; Mexican dollars, 51c, San Francisco; 47<sup>1</sup>/<sub>2</sub>c, New York.

COPPER.—New York: Standard, \$15.50; Lake, 1 to 3 casks, \$15.37<sup>1</sup>/<sub>2</sub>@15.50; Electrolytic, 1 to 3 casks, \$15.37<sup>1</sup>/<sub>2</sub>; Casting, 1 to 3 casks, \$15.25. San Francisco: \$16.00. Mill copper plates, \$17.00; bars, 18@24c. London: £67 15s spot per ton.

LEAD.—New York, \$4.55; Salt Lake City, \$3.50; St. Louis, \$4.12<sup>1</sup>/<sub>2</sub>; San Francisco, \$4.50, carload lots; 4<sup>1</sup>/<sub>2</sub>c 100 to 4000 lbs.; pipe 6<sup>1</sup>/<sub>2</sub>c, sheet 7, bar 5<sup>1</sup>/<sub>2</sub>c; pig, \$4.85. London: £12 12s 6d per long ton.

SPELTER.—New York, \$6.20; St. Louis, \$6.30; London, £24 17s 6d per ton; San Francisco, ton lots, 6<sup>1</sup>/<sub>2</sub>c; 100-lb lots, 7c.

TIN.—New York, pig, \$29.25@29.75; San Francisco, ton lots, 30c; 500 lbs., 30<sup>1</sup>/<sub>2</sub>c; 200 lbs., 30<sup>1</sup>/<sub>2</sub>c; less, 31c; bar tin, 32<sup>1</sup>/<sub>2</sub>@35c. London, £130 15s spot.

PLATINUM.—San Francisco, crude, \$18.50 per oz.; New York, ingot, \$19.50 per Troy oz. Platinum ware, 75@82c per gram.

QUICKSILVER.—New York, \$40.00@41.00, large lots; London, £7 15s; San Francisco, local, \$39.00 per flask of 75 lbs.; Denver, \$45.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6<sup>1</sup>/<sub>2</sub>c; extra, 17<sup>1</sup>/<sub>2</sub>c; genuine, 31<sup>1</sup>/<sub>2</sub>c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 19.50c; San Francisco, Plumbers', 100-lb. lots, 16.25c.

ZINC.—Metallic, chemically pure, 50c; dust, 45c; 10c; sulphate, 10c.

NICKEL.—New York, 55@60c per lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c per lb.; 100 lbs., 35c; 1000 lbs., 34c; ton lots and over, 33c, Pittsburgh. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburgh.

### STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$16.85@17.10; gray forge, \$15.85; San Francisco, bar, 3c per lb., 3<sup>1</sup>/<sub>2</sub>c in small quantities.

STEEL.—Bessemer billets, Pittsburgh, \$27.00; open hearth billets, \$27.00; San Francisco, bar, 7c to 12c per lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6<sup>1</sup>/<sub>2</sub>c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, 1c per lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, 1c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6<sup>1</sup>/<sub>2</sub>c; do. in kegs, 7c.

LUMBER.—(Retail): Pine, ordinary sizes, \$24.00@25.00; extra sizes higher; redwood, \$28.00@30.00; lath, 4 feet, \$4.50@5.00; pickets, \$21.00; shingles, \$2.50 for No. 1 and \$2.25 for No. 2; shakes, \$13.50 for split and \$15.00 for sawed; rustic, \$28.00@35.00.

NAILES.—This week the basic prices are: Wire, \$2.77; Cut, \$3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, \$3.35; Cut, \$3.55; 10d to 16d, Wire, \$3.45; Cut, \$3.35; 8d, Wire, \$3.50; Cut, \$3.50; 6d and 7d, Wire, \$3.60; Cut, \$3.60; 4d and 5d, Wire, \$3.70; Cut, \$3.70; 3d, Wire, \$3.85; Cut, \$3.85; 2d, Wire, \$4.10; Cut, \$4.10. Special rates for carload lots.

LIME.—Santa Cruz, \$1.25 country, \$1.25 city per bbl.

CEMENT.—Imported, \$2.15@2.65 per bbl.; California, carload lots, \$2.10 f. o. b. at works; small lots, \$2.40 per bbl. in sacks, 4 sacks to bbl., 10c for each sack returned.

### GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 8<sup>1</sup>/<sub>2</sub>c; Hallett's, 8<sup>1</sup>/<sub>2</sub>c; San Francisco, 1000-lb. lots, 9c; 300@500-lb. 9<sup>1</sup>/<sub>2</sub>c; 100-lb. lots, 10<sup>1</sup>/<sub>2</sub>c.

COAL.—San Francisco, coast, yard prices: Wellington, \$8.00; Seattle, \$6.50; Coos Bay, \$5.50; Southfield, \$8.00. Cargo lot, Eastern and foreign: Wallsend, \$7.50; Brymbo, \$7.50; Pennsylvania, hd., \$14.00; Scotch, \$8.00; Cumberland, \$13.00; Cannel, \$8.50; Welsh Anthracite, \$13.00; Rock Springs, \$8.50, long ton; Colorado Anthracite, \$14.00. Coke, \$10.50 per ton in bulk, \$13.00 in sacks; Sunnyside, \$8.50, long ton.

OILS.—Linsseed, hoiled, bbl., 55c; cs., 60c; raw, bbl., 53c; cs., 54c; Lucol oil, hoiled, bbl., 50c; cs., 55c; raw, bbl., 48c; cs., 53c. Kerosene—Pearl, per gal., 19c; Astral, 19c; Star, 19c; Extra Star, 22c; Eocene, 21c; Elaine, 25c; Water White, in bulk, 12<sup>1</sup>/<sub>2</sub>c; Mineral Seal, iron bbls., 18c; wooden bbls., 20<sup>1</sup>/<sub>2</sub>c; cs., 24c; Mineral Sperm, cs., 26<sup>1</sup>/<sub>2</sub>c; Deodorized Stove Gasoline, hulk, 16c; do., cs., 22<sup>1</sup>/<sub>2</sub>c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naptha or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19<sup>1</sup>/<sub>2</sub>c; Lard Oil, E. W. S. h., bbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 63c; Bleached, do., 57c; Whale Oil, cs., 52@57c.

POWDER.—F. o. h. San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15<sup>1</sup>/<sub>2</sub>c; less than one ton, 17<sup>1</sup>/<sub>2</sub>c. No. 1\*, 60%, carload lots, 13<sup>1</sup>/<sub>2</sub>c; less than one ton, 15<sup>1</sup>/<sub>2</sub>c. No. 1\*\*, 50%, carload lots, 11<sup>1</sup>/<sub>2</sub>c; less than one ton, 13<sup>1</sup>/<sub>2</sub>c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9<sup>1</sup>/<sub>2</sub>c; less than one ton, 11<sup>1</sup>/<sub>2</sub>c. No. 2\*\*, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2.00 per keg.

CAPS.—3x, \$5.50@6 per 1000; 4x, \$6.50@7; 5x, \$8@8.50; Lion, \$9@9.50, in lots not less than 1000.

FUSE.—Triple tape, \$4.00 per 1000 feet; double tape, \$3.50; single tape, \$3.10; Hemp, \$2.75; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11c per set; 14 oz., 40s., 9<sup>1</sup>/<sub>2</sub>c.

CHEMICALS.—Cyanide of potassium, 98%-99%, joh-hiog, 23@24c per lb.; carloads, 23@23<sup>1</sup>/<sub>2</sub>c; in tins, 30c; soda ash, \$2.00 per 100 lbs.; hyposulphite of soda, 3@3<sup>1</sup>/<sub>2</sub>c per lb.; caustic soda, in drums, 3@3<sup>1</sup>/<sub>2</sub>c per lb.; Cal. soda, hbls., \$1.10@1.20 per 100 lbs.; sks., 90c@1.00; chlorate of pot-

ash, 12@13c; nitrate of potash, 6<sup>1</sup>/<sub>2</sub>@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2<sup>1</sup>/<sub>2</sub>@2<sup>3</sup>/<sub>4</sub>c; powdered sulphur, 2<sup>1</sup>/<sub>2</sub>@2<sup>3</sup>/<sub>4</sub>c; flour sulphur, French, 2<sup>1</sup>/<sub>2</sub>@—c; alum, \$2.00@2.25; California refined, 1<sup>1</sup>/<sub>2</sub>@2c; sulphide of iron, 8c per lb.; copper sulphate, 5<sup>1</sup>/<sub>2</sub>@5<sup>3</sup>/<sub>4</sub>c; chloride of lime, spot, \$2.50@2.75; sulphuric acid, in carboys, 66% B, 1<sup>1</sup>/<sub>2</sub>@2c per lb.; nitric acid, carboys, 8c per lb.

BORAX.—Concentrated, 6@7c per lb.; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

BONE ASH.—Extra No. 1, 5@6c per lb.; No. 1, 4@5c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c per lb.

MOLYBDENUM.—Best, \$2.75 per lb.

CHROMIUM.—90% and over, 7<sup>1</sup>/<sub>2</sub> per lb., 80c.

PHOSPHORUS.—American, 70c.

SILVER.—Chloride, per oz., 90c@1.00; nitrate, 55c.

RED LEAD.—500 lbs. and over at one purchase, 7<sup>1</sup>/<sub>2</sub> per lb., 7c; less than 500 lbs., 7<sup>1</sup>/<sub>2</sub>c.

MAGNESIUM.—Pure, N. Y., \$1.60.

MANGANESE.—Per lb., \$2.75.

SODIUM.—Metal, 50c.

BISMUTH.—Subnitrate, 7<sup>1</sup>/<sub>2</sub> per lb., \$2.10.

URANIUM.—Oxide, 7<sup>1</sup>/<sub>2</sub> per lb., \$3.50.

MERCURY.—Bicchloride, 7<sup>1</sup>/<sub>2</sub> per lb., 77c.

TUNGSTEN.—Best, 7<sup>1</sup>/<sub>2</sub> per lb., \$1.25.

FIRE BRICK.—Domestic, carloads per 1000, f. o. b., factory square, \$25.00; soap and split, \$22.50; arch and wedge, \$27.50; skewback, \$30.00; circle, \$32.00.

FIRE CLAY.—Domestic, per ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. h., factory, \$8.50.

## Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

CAR VENTILATORS.—No. 779,755. Jan. 10, 1905. J. E. Armstrong, Santa Cruz, Cal. This invention relates to a means for ventilating cars and the like in such a manner as to remove the vitiated air from the apartment and at the same time prevent the introduction of air in such a manner as to create disagreeable drafts. The invention consists in so mounting the window or closure of the window opening that it may be moved either in its entirety or sectionally, so that a proportionately small opening is presented in the direction toward which the train is running or from which the air draft proceeds, and a larger opening is presented in the opposite direction, so that it will produce a species of suction and remove the air from the compartment, while the suction thus set up through the large and small openings will not be such as to cause a draft within the apartment.

CAN TESTING MACHINE.—No. 779,719. Jan. 10, 1905. P. Kruse, Astoria, Or. One-third assigned to the Astoria Iron Works, of Astoria, Or., a corporation. This invention has for its object the protection of a machine for testing sheet metal cans, and it consists in devices for automatically receiving the cans and mechanism for holding or clamping the can against a pressure chamber. Another object of the invention is to provide improved means for automatically finding and discharging leaky cans through a false bottom in the runway provided for delivering tight cans, thereby dispensing with an operator. A further object of the invention is to provide improved means for testing cans without wetting them, thereby dispensing with a drying machine. It consists in various novel devices and combinations of parts which form the improved and completed machine.

SAW FILING MACHINE.—No. 780,232. Jan. 17, 1905. M. P. Schell, San Francisco, Cal. Assigned to Folkers Saw Filing Machine Co. of San Francisco, Cal., a corporation. This invention relates to improvements in saw filing machines, and particularly to that type of machines employing power driven helical file members. The object of the invention is to provide a positive means for advancing the file carriage and rotating the file members at uniform speed and to provide a novel means of mounting the files whereby they will act upon the teeth in a manner to produce the best result in conformity with usual saw setting methods.

FLYWHEEL BRAKE.—No. 780,184. Jan. 17, 1905. A. G. Hubbard, San Francisco, Cal. One-half assigned to B. S. Hubbard of San Francisco, Cal. This invention relates to a brake which is especially designed for application to fly and other wheels connected with machinery where it is desirable to make quick stops and releases. The device comprises a shoe having a frictional surface thereon, there being inclines carried by the lower part of the shoe and corresponding fixed inclines upon which those carried by the shoe are slidable; a spring pressed foot lever and connection between it and the shoe whereby the latter is advanced and raised into contact with the wheel rim and an adjustable stop to limit the forward movement of the shoe.

BELT CONVEYER.—No. 780,145. Jan. 17, 1905. L. K. Vaughan, Oroville, Cal. This invention relates to improvements in street belt conveyers for handling coal, sand, gravel and like coarse heavy granular matter, and pertains especially to tailings stackers for gold dredgers. The object of the invention is to prevent the disastrous wear that now occurs with belt carriers of the above type, and thereby save or lessen to a great degree the expense of frequent renewal of the belts. It comprises an endless belt conveyer having a separate and readily removable central protective shoe or wearing pad on its supporting surface, said pad of lesser width than the conveyer, and other details of construction.

AERIAL CABLEWAYS.—No. 780,127. Jan. 17, 1905. J. S. Rees, Loyalton, Cal. One-half assigned to W. S. Lewis of Loyalton, Cal. This invention relates to aerial cableway, and especially to a system adapted for logging purposes. The object of the invention is to provide a suitable logging system which shall be simple and cheaply and easily installed, which can be strung to indefinite lengths through the forests and made to transport logs either bodily or by dragging them along the ground, and which can be run on irregular lines and made to turn as many corners as necessary or desired.

## New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING JANUARY 17, 1905.

780,475.—SAW.—S. J. Benz, San Francisco.  
780,157.—BLOCK DIRECTORY.—G. Cadenasso, San Francisco.  
780,322.—TOOL HOLDER.—M. N. Callender, San Francisco.  
780,159.—CLUTCH.—W. H. Corbett, Portland, Or.  
780,031.—CONCENTRATOR.—F. E. Forster, Clifton, Ariz.  
780,171.—TALKING MACHINE.—F. C. Hassett, Kelso, Wash.  
780,184.—FLYWHEEL BRAKE.—A. G. Hubbard, San Francisco.  
780,038.—PIPE GRIP.—E. G. Huntington, Santa Ana, Cal.  
780,293.—LEACHING.—T. B. Joseph, San Francisco.  
780,211.—AXLE.—A. C. Massey, Los Angeles, Cal.  
780,373.—WATER ELEVATOR.—T. H. McDonald, Elk Grove, Cal.  
780,319.—MUSIC LEAF TURNER.—F. B. McMillan, San Francisco.  
780,121.—CAN OPENER.—T. T. Merriman, Medford, Or.  
780,127.—AERIAL CABLEWAY.—J. S. Rees, Loyalton, Cal.  
780,228.—STOVE.—E. H. Richardson, Ontario, Cal.  
780,232.—SAW FILING MACHINE.—N. P. Schell, San Francisco.  
780,144.—RIPPER.—J. K. Van Winkle, Sumpter, Or.  
780,145.—BELT CONVEYER.—L. K. Vaughan, Oroville, Cal.  
780,467.—BLAST HOLE LOADER.—W. T. Wright, Bisbee, Ariz.  
39,266.—DESIGN.—N. J. Boyle, Los Angeles, Cal.

## Unwatering the Comstock.

When the lower levels of the Comstock lode, Virginia City, Nev., were abandoned years ago, there were few that even entertained a hope that the bottom of the deep workings would ever be seen again. Floods of scalding water, and the constantly increasing expense, together with the fact that no important bonanza was in sight, were the causes which led to the abandonment of the lower levels, and the workings were permitted to fill until the water, rising, flowed out of the Sutro tunnel. After years of idleness, below that level, the several companies in the Virginia City section of the lode organized as the Comstock Pumping Association. In 1899, the hydraulic elevator was successfully installed in the Con. California & Virginia shaft and, in a few months, the water of this central section had been lowered several hundred feet and mining was resumed again below the adit level—the Sutro tunnel. In time a series of electrically driven pumps was installed on the 2150 level of the Con. Virginia mine, in a great chamber cut out of the rocks and substantially timbered. These pumps took the water raised from the 2350 level by the hydraulic elevator, and sent it to the Sutro tunnel level. It was demonstrated that an equipment, costing less than one-tenth of some of the single installations of the Cornish type which had been placed on several of the mines, was abundantly able to do the work of half a dozen of these former great installations. The introduction of electric power on the Lode at once reduced the cost of power from \$20 per horse power per month to \$7 per month—a very material reduction in expense.

The illustration of the electric pump on this page is that of the latest installation on the Comstock. It is at the Ward shaft, in the Gold Hill section, and by its use it is hoped to unwater the workings of that portion of the lode to the bottom of the shafts which were sunk there prior to their abandonment, when an unexpected scalding flood from the Exchequer workings drove the miners from the lower portion of the mine. This pump is fully described elsewhere herein.

Those familiar with the conditions on the Comstock, and acquainted with the difficulties to be overcome,

Direct Driven Electric Mine Pump, Ward Shaft, Gold Hill, Comstock Lode, Nevada. (See Page 73.)

## Progress in Africa.

It is only ten years since Rhodesia came to be known to the civilized world. In the maps of a decade past the portion of South Africa now known as Rhodesia was marked Matabele Land. Rumors came out of that unknown region through the medium of hunters, missionaries and traders that the land abounded in ancient mines and was rich in gold. As long ago as 1860 Dr. Livingstone, the explorer, said of the region about Tete, a native village on the Zambesi, that the entire country over an area several

the ancient resources. One of the engravings on this page illustrates the march of civilization into the heart of the "Dark Continent" from the southward. The plant presents an appearance not unlike plants for like purposes in the older civilized parts of the world. To the northward, beyond the Zambesi river in the Congo Free State, copper, iron and gold mines are being developed, and the influences of these two regions are sure to radiate outward, and in time the entire country between them, at present almost unknown and inhabited only by the natives, will be settled by the progressive Caucasian race and be.

A Gold Mill and Cyanide Plant, Rhodesia, South Africa. (See Page 72.)

confidently anticipate the success of this newest enterprise, and it may not be many months before the work of exploration will be resumed in the old deep workings—and the shafts will probably be sunk deeper than before.

miles square showed evidence of having been worked for alluvial gold. At present little or nothing is being said of Tete and its vicinity, but about Bulawayo the ancient workings have been explored, and there are numerous companies at work there developing

come the center of great industrial life. Railways are already being built through this country, and this, together with the development of the vast power of the great falls of the Zambesi—Victoria falls—will hasten its settlement and civilization.

THE cause for the direction of an air current being reversed through shafts connected by mine workings is not always clearly evident, but such does at times occur. At the time of a great fire in the Yellow Jacket mine at Gold Hill, on the Comstock, an upcast shaft became a downcast. At a fire in the Charters Towers district, Queensland, Australia, which occurred several weeks ago, a similar occurrence was noted. In this latter instance the cause of the reversal of the air current was fully determined. Some believed it to be due to the turning a stream of water down the shaft, which imprisoned a large volume of air as it fell, forcing the air current in an opposite direction to that which it had previously followed naturally. Others thought it due to the falls of rock and debris in the lower portion of the shaft which bulkheaded the workings and forced the imprisoned air and the gases of combustion to rise through the downcast shaft. Subsequently it was learned that it was due to falls of the hanging wall. In this fire a number of miners lost their lives by inhaling carbon dioxide—the result of the burning of the timbers. In this connection the official inspector of mines makes the statement that neither the management nor the miners were aware that burning timber could supply this deadly gas, and did not realize the danger attending an effort to extinguish the fire by working in its vicinity underground. Miners should be instructed in these matters, and in mine ventilation generally. When mine fires occur men sometimes attempt heroic deeds which in times of less excitement and danger they would not contemplate for a moment, but the miner has never yet been found deficient in courage when the lives of his fellow workmen were at stake. Some make the venture to save lives first, and study the chemistry of combustion of mine timbers later if they have the opportunity.

## State Mining Legislation.

In a recent decision of the Supreme Court of the United States Justice Brewer sustains a decision of the Montana Supreme Court, which is of importance, in that it recognizes as constitutional the legislation of the several States in making laws not in conflict with the Federal Statutes. The United States law fixes the minimum requirement in making locations, but to this requirement the State Legislatures, and the miners themselves of the organized districts, may lawfully make rules prescribing the acts necessary to constitute a valid claim location. Some States require a stated amount of work to be performed, and other acts done within a given period—sixty to ninety days—which is really a part of the act of location, and these requirements are in addition to those required by the Federal Statutes. Montana is one of the States in which this supplementary legislation has been enacted. The decision of the United States Supreme Court above referred to was in the case of the Butte City Water Company plaintiff in error against B. Baker, in which appeal was taken from the decision of the Montana court. In conclusion Judge Brewer said:

The Montana statute, among other supplementary regulations, provided that the declaratory statement filed in the office of the clerk of the county in which the lode or claim is situated must contain "the dimensions and location of the discovery shaft, or its equivalent, sunk upon lode or placer claims," and "the location and description of each corner, with the markings thereon." A failure to comply with these regulations was the ground upon which the Supreme Court of Montana held the location invalid. It is contended that these provisions are too stringent, and conflict with the liberal purpose manifested by Congress in its legislation respecting mining claims. We do not think that they are open to this objection. They certainly do not conflict with the letter of any Congressional statute; on the contrary, are rather suggested by Section 2324. It may well be that the State Legislature, in its desire to guard against false testimony in respect to a location, deemed it important that full particulars in respect to the discovery shaft and the corner posts should be at the very beginning placed of record. Even if there were no danger of false testimony it was not unreasonable to guard against the resurrection of incomplete locations when by subsequent explorations mining claims of great value have been uncovered.

We see no error in the rulings of the Supreme Court of Montana, and its judgment is affirmed.

This decision clearly confirms the right of the several States to make mining laws not in conflict with the existing laws of the United States.

## Perverting the Facts.

One of the most regrettable things about many of the reports made by self-styled mining engineers is the distortion of facts. It is no uncommon thing to see paragraphs culled from official reports of State officers and the whole woven into an interestingly plausible fabric of misrepresentation. It may be that the property which is the subject of the report has intrinsic value, or it may remain to be demonstrated that it possesses any value at all, but the astute promoter draws attention to the indisputable fact that the property in question lies directly between two noted mines, each of which has produced millions of dollars. While this statement is true, it may be also misleading, as it may be that the two noted mines are on two distinct lodes or belts many miles apart and neither of them have anything in common with the property described by the promoter, the only claim to distinction being that it lies between them. Statements contained in these reports are often apparently so straightforward and honest as to deceive those unfamiliar with the section in which the mine is situated. Very few mines are developed and equipped without assistance from others not originally owners, and while, undoubtedly, the failures in mining outnumber the successes, this fact is largely due to the carelessness of the investors in investigating the enterprise in which they are solicited to take stock or an interest. So long as promoters confine their statements to facts, without distortion or misrepresentation, and do not so state facts as to be misleading, no one can object to the attempt to secure capital for equipment and development of new mining enterprises by the sale of stock in such concerns. Other enterprises in industrial lines secure

needed financial aid in this manner and there is no reason why mining should be an exception if no misrepresentations are made, for it is the intent to deceive that renders this class of promotion obnoxious to the real friends of the industry of legitimate mining.

## Careless Use of Powder.

A bill was recently introduced in the State Senate of Illinois providing that the operators of mines in that State shall provide men whose duty it shall be to load and fire holes. In addition to this the shot firer shall post conspicuously a bulletin giving the number of holes loaded, the number of shots missed, and giving the reason and location of such shots, if any occur. A bill of this character cannot fail to be of usefulness. The indiscriminate handling of powder and caps in mines without particular restrictions is prolific of many serious accidents, and no single legislative measure could be of greater service to large mines than that requiring that the loading and firing of holes be done by men whose particular business it is to attend to this branch of the underground work. Many mines employing a large number of men have "gunners," whose duty it is to load all holes and fire them, as contemplated in the Illinois bill, but there are many others who do not consider it necessary, but it is a noteworthy fact that there are fewer fatalities due to premature blasts, missed holes, and explosion of the powder stored at the loading bench on the level, where there is a gunner, than where no such man is employed. Miners by long contact with nitro powder become careless and indifferent to the element of danger always present, and it is due largely to this fact that many disastrous explosions occur. In many instances miners, when left to their own discretion, employ much more powder than is really necessary to break the ground. Leasers and contractors understand these things better, generally, than miners who are employed by the day, and who have no occasion to use greater care or to exercise more economy. The contractor and leaser must pay for the powder he uses and takes this into consideration when charging a hole. In coal mining the overcharging of a hole is fraught with much more danger and more grave consequences, and yet in metal mines the results of careless handling of powder are sufficient to justify some stringent means of enforcing a proper recognition of this danger upon the mine management and upon the miners themselves.

## Mine Taxation.

A bill has been recently introduced in the Washington State Legislature, the purpose of which is regulating the taxation of mines and mining property. It is provided in this bill that the net valuation of the mine shall be the basis of taxation, determined by measurement of "ore in sight." As this would naturally contemplate an expert examination of every mine in the State—a political impossibility—the bill requires that the superintendent, manager or owner shall make an affidavit of the value of ore in sight at a stated date, when assessment is to be fixed. The idea is ingenious, but has the appearance of being impracticable, for the reason that the net value of a mine changes with every shift's work, not materially, perhaps, in so short a time, but the mine manager, who is disposed to take advantage of this fact, could so manipulate his development work that, at the time of year when assessment is to be made, the mine would have little or no net value, and a few months later it may possibly have exposed many thousands of dollars' worth of ore. The bill further contemplates the assessment and taxation of improvements. In the mining industry the conditions are such that a mine may have improvements worth half a million dollars or more, and still the mine be unprofitable, while a mine worked with an outfit worth only a few hundred dollars may be at the same time a famous producer. There have been many instances illustrating both of these conditions within two or three years in southern Nevada, and they may be seen there to-day. The taxation of mining property is one of the most difficult matters to adjust in an equitable manner, and all of the mining States have had more or less difficulty with this class of legislation.

## CONCENTRATES.

GOLD most commonly occurs associated with quartz, but all quartz does not contain gold, and much gold occurs where quartz is scarce or absent entirely. Many dike rocks contain gold with no visible quartz.

ASBESTOS is found in the serpentine rock in various parts of California, but present demand is not sufficient to warrant extensive development, or the placing of machinery. The most of the crude asbestos comes from Canada.

TIN SULPHIDE is known to occur in a number of localities, but is not a common mineral. Tin is usually found in veins in the form of the oxide of tin, cassiterite, which seem to have been the original form of the mineral, and is not the result of its alteration from the sulphide as is the case with most other oxides.

THE largest diamond ever discovered is that recently taken from the Premier mine, near Pretoria, in the Transvaal, South Africa. It weighs 3022 carats—about 20.2 ounces Troy. Its value has not yet been absolutely determined. It is described as a diamond of unusual purity and brilliancy, features often lacking in large diamonds.

SHAFTS may be sunk several hundred feet without timbers, if the ground stands well. On Stockton ridge, near Mokelumne Hill, Calaveras county, Cal., shafts 250 feet in depth, sunk in early 50s, are open to-day from top to bottom, and not a stick of timber was ever in them for support of the walls. Those shafts are circular, and cut through volcanic mud and tuff. In the Calico mining district of California there are shafts 200 to 300 feet deep in which there have never been any timbers.

WHERE possible, ore should be broken in a breaker near the shaft or mouth of the tunnel, and delivered to a bin beneath, from which it may be drawn into cars and hauled to the mill, where it may be distributed to any portion of the bins where it is required. The placing of a breaker in the mill should be avoided wherever possible, and where it cannot be avoided it should be set on a separate frame of timbers, which are not connected with the main mill frame.

ONE of the most important things to give particular attention in the running of a machine drill is to see that it is kept well oiled, particularly when the machine is new. Where the distance from the floor to the back of the drift or slope is very much greater than the length of the drill column it is a good idea to build a crib-like structure 3 or 4 feet square, as a base for the blocking, and not depend wholly on a pile of small blocks with too small a superficial area, which will give an insecure foundation.

THE most important tests of steel hoisting rope are those for bending and tensile strength. A good rope must not show a variation of more than 2% in these tests. The most important of all are the bending tests. A wire rope must not be bent over too small a sheave or drum, as it causes the interior strands to wear upon each other, and the unequal strain upon the several strands of the rope may cause it to break at a time when the tensile strength of all the strands still possesses a large factor of safety.

ABOUT 2000 miles of roads are treated with crude petroleum in California. The railroad companies have also oiled hundreds of miles of their tracks for the purpose of laying the dust. The proper oil to use for this purpose is that containing a high percentage of asphalt. After the roadway has been sprinkled liberally with oil the petroleum will collect in ruts and other depressions, forming pools. This is a waste of oil, and to secure good results the application of the oil should be followed by sprinkling enough sand over the roadway to take up the surplus oil. The sand absorbs the oil and forms an artificial asphalt rock.

CINNABAR is one of the most stable of the sulphides of the base metals. It is commonly found in the surface of the veins containing mercury, and in an unoxidized condition. What is known as inflammable cinnabar occurs in the quicksilver mines of Idria, Austria, and is technically called idrialite. In the pure state it is white and has a crystalline structure, but in nature is always impure, being associated with cinnabar, clay, pyrites gypsum, etc., in an earthy, dark-colored material which is combustible—probably a variety of bitumen—and it is owing to the presence of mercury in the mass that the mineral has been called inflammable cinnabar.

USUALLY ore which has been exposed for a long time on dumps, where it has had an opportunity to oxidize, is easier to treat by the cyanide process than the ores recently extracted from the mine. This is also applicable to tailings, and is due, doubtless, to the repeated washings from rains, which wash out the sulphates as fast as they are formed by oxidation. Some silver ores are amenable to cyanide treatment, and others are rebellious. The time required is usually too long and the consumption of cyanide so high that it is usually not at-

tempted. As a general thing other processes are better adapted to the treatment of silver ores than the cyanide process. At Dayton, Nevada, gold-silver ores and tailings are being successfully treated by a chloro-cyanide process.

IN many instances where a gold-bearing vein has been faulted, it is found that the ore is far richer just above the fault than it is below it. It seems due to secondary processes, which have caused the gold to accumulate at this place. In one mine, known to the writer, a quartz vein was faulted a distance of 18 inches. The vein was horizontal in slate. The fault plane was nearly vertical. Although the vein contained gold, it was only in small amount, and the slates showed no gold and little minorization by iron sulphide. In the fault fissure, however, between the fractured ends of the vein, the material consisting of granulated quartz, slate and gouge for a distance of about 150 feet the gold values were high. Two men took out several thousand dollars in drifting 70 feet. Without doubt this deposition of gold was secondary, and may have been derived from the vein. There was no direct evidence, however, that such was the case.

THE wide difference in the cost of accomplishing the same kind and amount of work in two mines situated in the same district probably represents the difference in the character of the rock passed through. There are so many factors which go to make up the cost of shaft sinking that no close figures can be given without full knowledge of the conditions. Generally speaking, the cost of sinking a two compartment shaft 5x10 feet in the clear, in fairly easy ground, and fully timbered, should not greatly exceed, if it reaches \$40 per foot, with wages at \$3 per day. The amount of water encountered is important, and also the style of timbering adopted. The work should be so arranged as to lessen the lost time to a minimum. Lost time is an important factor. There are waits on powder gas, on skips, on men and timbers, which should be avoided as far as possible.

IN the case of sinking the shaft through loam and quicksand overlying rotten granite, it may be possible to get the shaft started and completed into the solid rock by first driving sheet piling—piles consisting of 3-inch plank and provided with tongue and groove or dovetailed joints. These fit closely and when driven to bedrock will, in all probability, render the structure water tight, when the excavation may proceed, the water being pumped or hauled out. The freezing method is also applicable to this condition, but the former method is cheaper and more quickly available, as the sheet piling can be made by carpenters on the ground, and a pile driver could be improvised to drive the piling. If the loam and sand are too deep for one line of piles a second line may be driven inside the first, when the excavation has proceeded far enough to justify this course.

THE amount of solution to be precipitated in cyanide works per ton of ore treated varies from  $\frac{1}{4}$  ton in works of large capacity (600 tons daily) to 1 ton or over in small plants, treating 100 tons or less per day. It is the practice to pass about 26 cubic feet of solution per hour through precipitation boxes 20 to 24 feet in length, 26 inches deep and 36 inches wide. A means of calculation is based on the above amount of flow as follows: For each ton of solution (32 cubic feet) to be precipitated per hour, 21 cubic feet are to be provided in the zinc box, and each compartment of the series is to be designed to hold 1 cubic inch of zinc for every ton of solution treated monthly. A plant treating about 30,000 tons of solution monthly should have precipitation boxes each holding 30,000 cubic inches of zinc shavings or, say, 24 inches deep, 36 inches square on the bottom.

WULFENITE is molybdate of lead—a mineral not uncommon in lead producing mines of the Western States, particularly those of Arizona, New Mexico, Nevada, Utah and southern California. It is also found in Mexico. It often occurs in groups and masses of brilliant amber, yellow to reddish crystals, of great beauty. Sometimes the mineral is dull and earthy looking. The ore contains molybdenum trioxide 39.3%, lead oxide 60.7%. Large amounts of this mineral have been sent together with other lead ores, to the smelters, from Castle Dome in Arizona near the Colorado river, and from other Arizona mines. As far as known to "Concentrates," wulfenite has never been used as a source of molybdenum. Unless the ore exists in the form of handsome cabinet specimens, it is probably not worth more than the value of the lead it contains; its commercial value must be determined consequently in the same manner as other ores of lead.

THE "reefs" of the Witwatersrand are beds of conglomerate or puddingstone intercalated in sandstones and quartzites, and are in no sense to be regarded as veins, though worked in a similar manner to veins. The origin of the gold, which is said to be wholly in the cementing material, is not unlike that of gold in veins—that is, it has been carried into the open spaces in the conglomerate in solution and there deposited when proper conditions were found. There are numerous dikes of diabase cutting these conglomerate beds, and they are often found disturbed by faulting. It is probable, however, that the gold was introduced prior to the faulting, and that the dikes have in some manner influenced the deposition of the gold. There are large

numbers of these reefs of varying thickness, but comparatively few carry gold, and of these only a small number are payable. The deepest shafts and bore holes have intersected the reefs nearly 8000 feet from the outcrop.

IN surveying the mine the surveyor should establish marks which shall be permanent. Marks on timbers (nails driven in at stated places) are too easily moved to make them altogether reliable. One of the best methods of fixing points in underground surveys is by drilling a short hole at the point, inserting a wooden plug and driving a slender nail at the exact spot determined by the cross hairs of the transit. In shaft work it is often inconvenient to do this, and in such cases points on timbers are used, but in the case of important underground connections, where large expenditures are involved, it is best to resurvey the workings from the surface where these points have not been fixed in immovable rocks, for timbers often shift and may throw a line out sufficiently to cause a great deal of trouble in making distant connections. The transit points at the collar of the shaft should be determined by the bearing of distant fixed objects and not depend upon anything in the immediate vicinity of the shaft, as the ground often settles about the shaft sufficiently to cause serious errors in the survey.

THE principal ores of nickel are genthito, a nickel silicate, color pale apple green or yellowish. It has a resinous luster; garnierite, also a silicate, consisting chiefly of hydrated silicate of magnesium and nickel, color bright apple green, pale green to nearly white. It has a dull luster, is sometimes greasy to the touch, and some varieties adhere to the tongue; niccolite, or copper-nickel, also containing a little cobalt and arsenic, being a nickel arsenide, usually massive and impalpable (without visible grain), luster metallic, color pale copper red, streak pale brownish black. Pyrrhotite—the magnetic sulphide of iron—often contains nickel and cobalt, is usually associated with nickel ores. The presence of nickel, cobalt, manganese and zinc in an ore can generally be detected from each other in an ore by adding to the acetate solution first ammonium chloride, then excess of ammonia, and finally an excess of potassium ferro-cyanide, when one of the following reactions will take place: A brown precipitate indicates manganese; a deep red solution, cobalt; no change in the cold, but on boiling a copper-red precipitate, nickel; no change in either hot or cold liquid. Add potassium ferro-cyanide, white precipitate, zinc.

THE story of the "Pegleg" Smith mine so commonly repeated has never been substantiated by any fact. It was first published in the latter 50's in a Los Angeles, Cal., paper, and has been repeated with variations for nearly fifty years, until it has come to be looked upon as a reality. It was supposed to be located somewhere between Fort Yuma and Warner's Pass and east of the Cuyamaca range, in San Diego Co., Cal. Hundreds of men have searched the desert in that region, near the old Butterfield trail, but without success, and many have lost their lives pursuing this ignis fatuus. There is little "sign" of mineral in that portion of the desert, and prospectors who contemplate a trip into that section would better confine their search to the territory between the Southern Pacific railroad and the Colorado river, where mineral veins are more or less abundant. As far as known, the United States Geological Survey has not yet issued a map of the Death Valley region, although the California State Mining Bureau has published maps of San Bernardino county and Bulletin 24 of the Mining Bureau, "The Saline Deposits of California," which contains maps and much information of the desert region of California.

IT would be difficult to arbitrarily state the amount of water required in a 5-stamp battery of ordinary type, without some knowledge of the character of the ore to be treated. It is customary to calculate upon providing at least 1000 gallons of water for each ton of ore crushed, although this amount may not be required. The quantity used is sometimes influenced by the amount of water available, and at many mills a scarcity of water necessitates pumping back a portion of that used, from settling reservoirs, for reuse. Many estimate the quantity of water per stamp for a stated period, but this seems an improper basis for such calculation, as in two mills equipped with the same weight stamps, etc., the tonnage crushed per stamp may vary greatly, due to the difference in the ore. In one, a stamp may crush 2.5 tons in twenty-four hours, and in the other 5 tons may be crushed. If the same amount of water is to be employed per stamp, it is obvious that in one mill twice as much water will be used per ton crushed as in the other. The tonnage treated is therefore the proper basis of calculation. Some ores require much more water than others, and often the subsequent treatment (concentration or cyaniding), has an important influence on the quantity of water that may be used. It is a common practice to add water to the pulp after it leaves the batteries, when concentration follows amalgamation, and still more water is added on the concentrating machines. Briefly, it may be said that the quantity of water used varies greatly—from 2.5 tons per each ton treated to as high as 16 tons. A small amount of water in the battery favors amalgamation but promotes sliming, while a large amount reduces sliming but permits only imperfect amalgamation, except on the most free milling of ores. The proper amount to be used should be determined by experiment.

## Mica; Occurrence and Uses.

Written for the MINING AND SCIENTIFIC PRESS.

The present demands of the electrical trade for mica and the working of the Barton mica mines in Piru and Lockwood creeks in Ventura county, California, suggest the timeliness of a description of the occurrence and mining of mica. India, Canada and the United States are the principal producers, and in addition considerable is obtained from Brazil.

India annually produces 1000 tons of mica, chiefly from Bengal and Madras. There are seventy mines being worked in the districts of Nellore, Nilgris and North Arcot, in Madras, employing about 3000 persons, including women. The sixty mines of Hazaribagh, Bengal, employ over 6000 persons. The government annually leases the land to the highest bidder.

The method of mining used by the natives is exceedingly primitive. Prospecting is done during the rains and all finds marked to be mined during the hot and cold season. Shafts 3 or 4 feet in diameter and about 40 feet deep are sunk every few feet along the deposit, first inclining a few feet to the left and then to the right, making a zigzag series of steps from top to bottom. Baskets of mica and refuse are hauled up these pits, usually by women seated on ladders or on a framework at the mouth of the pit, where it is hand-sorted and graded. Water is taken out in jugs passed from person to person on the ladders.

The blocks of mica raised from the mine are cleaned of quartz and feldspar in the stripping room, and

composition product, are often mined for pottery purposes. The mica books are usually irregularly distributed, being sometimes near the hanging or foot wall, often near the center, either clustered into bunches, or many feet apart.

There is a great difference in the quality of mica

off the cracked and stained mica. The free-splitting mica is trimmed and assorted, No. 1 being 4x6 inches, 6x8 inches, and larger; No. 2 from 3x4 inches to 4x6 inches; No. 3 from 2x4 inches to 3x4 inches, and No. 4 from 1x1 inch to 2x4 inches. The waste and trimmings are ground as scrap mica. C. F. Rice

Working of Newfound Mica M. Co., New Hampshire.

Crown Mica Mine, Custer, S. D.

when split the sheets are scribed and afterwards cut with a pair of shears along the scribing.

The mica occurs in small plates in many of the crystalline and metamorphic rocks of India, but the large crystals of commercial value occur with feldspar and quartz forming a coarse-grained pegmatite frequently intruded into older granites or into metamorphic rocks.

In Canada the phlogopite and biotite varieties are mined in the provinces of Ontario and Quebec, in the district about Ottawa, while transparent mica occurs at Tete Juane Cache and Canoe river in northern British Columbia. In Ontario there are mills at Sydenham, Ottawa, Kingston and Perth, which split the blocks of mica and thumb-trim it. Fortin & Gravel have a mine and mill at Hull; the Allan Gold Reef have a mine in Denny, the Glen Almond Co., in Portland East; the Vavassour in Hull, and F. N. Webster at the Cascades in Gatineau.

According to H. K. Scott in a paper read before the Institution of Mining and Metallurgy, mica occurs in workable quantities in the States of Goyaz, Bahia and Minas Geraes in Brazil. Near Santa Luzia de Carangola in Minas Geraes, the mica is found in pegmatite veins, lenses or dikes, in metamorphic schists, being generally altered to kaolin. The Fonseca and Coronel mines have been worked regularly, producing over fifty tons.

In the United States mica has been found and mined in most of the Appalachian States and many western regions where the country rock is mica schist intruded by pegmatite dikes. Its commercial sizes are found in about one-third of the States and Territories, but the chief producers are North Carolina, New Hampshire, South Dakota, New Mexico, Idaho, Virginia, Colorado and California. The United States Geological Survey, particularly in the twentieth annual report, has published much regarding the occurrence of mica. It is found usually as muscovite constituting about 10% of pegmatitic dikes in granites, gneisses, and micaceous and hornblende schists. These dikes are made up of quartz and feldspar in nearly equal proportions, the quartz being usually massive, although sometimes semi-crystallized and the feldspar being coarsely crystallized, the individual crystals occasionally weighing 1000 pounds or more. Muscovite mica is found generally disseminated throughout the quartz and feldspar in small scales and crystals and in large irregular crystalline blocks or "books" from a few inches to several feet in size. The feldspar and kaolin, its de-

scribed the work of the Newfoundland Mica M. Co. at Alexandria, Grafton county, in the MINING AND SCIENTIFIC PRESS of Feb. 23, 1901.

The mica in the Black Hills of South Dakota is usually good in color and free from iron specks, although sometimes the books are ruled and wedge shaped, making the sheets smaller and the splitting defective. The Crown mica mine, near Custer City,

found in Mitchell, Yancey, Jackson, Haywood and Macon counties, occurring in pegmatite dikes, of which 1% to 10% is mica. New Hampshire's chief mines are at Alstead, Cheshire county, also in Grafton and Sullivan counties. After the mica has been blasted out it is "rifted" or dressed by hand to split

was described in the MINING AND SCIENTIFIC PRESS of March 21, 1903, by D. Hennault. The Black Hills Porcelain, Clay & Marble Co. has done considerable work in Custer county. Custer and Pennington counties offer considerable opportunity for prospecting. The Etta mine, near Keystone, has been rather

closely studied by geologists. It was first worked for mica and afterwards for tin. The outcrop of the dike rises as a low rounded hill and is indistinctly concentric in structure. Dark-colored small scales of mica alternate with large blocks of muscovite in the matrix nearer the country rock, and next this is a coarsely semi-crystallized feldspar, in which is imbedded enormous crystals of spodumene, 30 feet or more in length. Toward the center of the dike the feldspar is less coarsely crystalline, and occurs with numerous smaller blocks of mica and quartz to form a greisen mass, in which most of the cassiterite is imbedded.

In New Mexico workable mica has been found in eastern Rio Arriba county and in San Miguel county, northwest of Las Vegas. The mica is good, but often badly "ruled," i. e., the sheets are cut partially or entirely through along lines parallel to the crystal faces. It often renders 75% of the mica valueless except for scrap. Considerable work has been done in the Cribhensville district.

The center of Idaho's mica industry is east of Moscow, in the Roberson mining district. The principal producers have been the Muscovite, Last Chance and Luella mines.

Amelia county is Virginia's chief source, although considerable has been done in Amherst, Bedford and Hanover counties. Much of Colorado's mica is "ruled." Deposits have been found near Floyd's station, 5 miles east of Idaho Springs; at the Terrell mine, 18 miles northwest of Golden; the Scheller mine in the same region; the Beers mine, 3 miles south of Idaho Springs; the Mi-Wot mine, northwest of Boulder; the Pearl mine, south of Leadville, and the Snively and High Creek mines, near Cripple Creek.

In California commercial mica has been reported from several places, one of the most important of which is on Piru creek in Ventura county, 53 miles

strike large blocks of mica in the first day's operations. Some of the larger mines are now being operated with more modern methods, including air drills, steam hoists and pumps. Dynamite is used in blasting, as it injures the adjacent mica less than did the powder formerly used.

The blocks as they are brought from the mine are sent to the storage or stripping room, where all foreign matter is removed from them. In describing further handling, J. A. Holmes says that by means of wedges and heavy knives these blocks are then split into sheets of varying thickness, which in turn are roughly trimmed and classified. These sheets are turned over to the scribes, where they are again split with knives and cut into the largest possible sizes. The cutters are supplied with patterns representing the different sizes and shapes in demand, and trim the sheets to these patterns with shears. Machines are also used. As the mica is cut it is graded and the different grades wrapped together in strong paper, in packages of one or more pounds.

But 90% of the mica taken from the mine is used as scrap mica. The ingenuity and skill in its utilization make an interesting study, which the writer was permitted to undertake through the courtesy of the Mt. Alamo Co. Many of the more perfect scraps and small sheets produced are cemented into larger sheets, being built up in a form to the desired thickness, with shellac as a cement. These "boards" are then rolled and subjected to a pressure of 2000 pounds to the square inch, and then kiln dried. These are afterwards molded, and are stamped into various shapes necessary for commutator segments, gaskets, etc. The machine for making electrical conduit first rolls asbestos paper on a rod, which is then covered with cotton cloth rolled in the opposite direction. This is passed through tar, covered with

pressure of the overlying schist were of any particular value. There are great variations in mica deposits. Most mica veins contain only small pockets of mica, which are soon worked out. The most economical way of mining mica is by steam or compressed air drills. It was thought until recently that mica could only be mined by hand drills, on account of the danger of breaking the crystals, but I have found by practical test that in drilling deep holes there is less liability of their destruction than with the shallow holes drilled by hand. The handling of the mica is very important in mica mining, as the value of the mica depends upon the size of the crystals, and an increase of the size (1 inch) makes a difference of \$1 a pound in the market value. If 10% of all the mica mined would cut into squares 2x2 inches and larger, up to 4x6 inches, it would be considered a good paying mine—the 10% being considered plate mica and the balance scrap mica. Plate mica is used as an insulation in all electrical machinery, such as dynamos, motors, transformers, etc. The scrap mica is ground into different grades and is used in insulating compositions in combination with binding material, also in the manufacture of wall paper pulp for decorative purposes; in paint, lubricating oils, and grease, fireproof material and in the adulteration of rubber.

### Magnetite as a Flux.

TO THE EDITOR:—Can you give any reason why magnetic oxide of iron cannot be used as flux in smelting? Or, if it can be, how? At the smelter at Ketchum, Idaho, are several carloads, sent there in the 80's for flux from Montana, which could not be used. At Mineral and at Cuprum, Idaho, the same class of ore was tried for fluxing, all with the same result, that the crucible would fill up with a

Tunnel of Mt. Alamo M. Co., Near Bakersfield, Cal.

Shop of Newfound Mica M. Co., New Hampshire.

from Bakersfield and from Lancaster, the shipping point. This is being extensively worked by the Mount Alamo Mining Co., with offices at 36 Geary street, San Francisco, Cal. The mica occurs in a large pegmatitic dike with a mica schist hanging and a granite foot wall. Mining has been conducted to a depth of 200 feet. So far the dike has been somewhat broken and faulted, but following the analogy of other mines it is hoped to get plate mica 2 or 3 feet square with increase of depth. The pegmatite dikes outcrop prominently, varying in width from a few feet to several hundred feet. The percentage of mica, as in the case of all such dikes, is variable with respect to quantity and in the percentage of plate mica in the individual blocks. Crystals of clean, clear mica are obtained that cut sheets from 2x3 inches to 4x10 inches, but the greater part of the mica is shipped as scrap to the company's factory in West Berkeley, Cal., where it is manufactured into mica segments, washers, tubes, troughs, mica conduits for electric wires, etc. They also grind mica and make mica pulp for wall paper.

The mining and preparation of mica for the market requires considerable skill and judgment gained only by experience. The mining operations in the United States are usually somewhat crude, being generally conducted on a small scale. The prospector upon finding a fair prospect for mica on the surface of a dike usually "follows the mica" as long as it is in sight, working entirely by hand with a couple of partners. Upon losing sight of the mica he tries in different directions until he strikes another lead, thus opening the mine in an exceedingly irregular manner known as "ground hogging." The irregular distribution of the mica so adds to the difficulty and uncertainty that the prospector frequently becomes discouraged and discontinues operations, while a second party starting the work anew will

ground mica, and then goes to the knitting machine, which surrounds it with a covering of knitted string. The whole is soaked in tar and mica and dried.

The most important product is ground mica. A. J. Hoskins, the superintendent for the Mt. Alamo Co., has devised an efficient grinder for this purpose, which may now be used for general grinding. It consists essentially of four revolving grizzlies moving within 1/2 inch of a corrugated iron surface covering the whole. The mica or other material is broken by centrifugal force. When broken it is carried out by an air blast and conveyed to trommels for sizing. The mica is ground from 6 to 100 mesh, 28 being used the most. This crusher should do much for the mica industry, as in the past this grinding has been difficult.

A. J. Hoskins, superintendent of the Mount Alamo M. Co., has sent the following communication on this subject to the MINING AND SCIENTIFIC PRESS:

To the advancement of electrical science is due the ever increasing demand for mica as an insulator. The mica of commerce is a silicate of aluminum and one of the important constituents of nearly all the granite formations. A mica vein is in reality a granite vein, of which mica is only a part. The difference between what is known as a mica vein and an ordinary granite vein is that in the mica vein each constituent is larger in proportion. In the mica vein, where the mica is large, the feldspar, quartz and tourmaline are also large proportionally. A mica vein is formed between schistose, or sedimentary rock, which acts as a hanging wall or foot wall. Mica usually crystallizes against the hanging wall, and generally within 3 feet of contact. The appearance of the hanging wall is an index of the value of the deposit—as I have found by examination of 150 deposits that only those deposits indicating extreme

past mass of magnetic oxide of iron, starting on the bottom and gradually working up, apparently melted, but not combined with anything else. On harring out the mass would appear like the ore before going into the furnace. It was not solid like a "sow," but could be easily broken with a hammer. I saw once in some paper that magnetic iron ore was being sent to some of the northwestern furnaces for flux, but could never learn how it was used.

Landing, Or., Jan. 28.

E. ANTZ.

As far as known, magnetite is not successfully employed as a flux in any of the blast furnaces of the United States in the reduction of copper or other ores. It has been stated that magnetite is used as a flux at Clifton, Arizona, in the copper furnaces of the Arizona Copper Co., but this is not the fact. In addition to the ore, matte and slag are employed in the charge, and no magnetite is used in the charge, or, if so, it is merely incidental, and in very small amount. The subject is an interesting one, and if magnetite is being successfully employed as a flux in the reduction of copper ores at any place, the MINING AND SCIENTIFIC PRESS will be pleased to learn of it, together with details as to furnace charges and results.—ED.

### Frothing in Zinc Boxes.

TO THE EDITOR:—"Concentrates" states that foaming in the zinc boxes is caused by an excess of lime or other alkali. In our experience foaming in the boxes ceased on the addition of more lime to the leaching vats. The excess of lime, however, caused

a greater consumption of zinc and an increase in the amount of white precipitate in the boxes.  
Cripple Creek, Colo., Jan. 25. F. F. REINER.

Without doubt the foaming of zinc boxes is due to various causes. F. L. Bosqui is of the opinion that foaming is chiefly due to the presence of organic matter in the material being treated—not an unusual thing in tailings. In such case the rootlets and other foreign organic matter should be screened and washed out as thoroughly as possible before treatment with solution begins.—Ed.

## Methods of Renewing Old Timbering at the Dives-Pelican Mine, Silver Plume, Colo.

NUMBER III.—CONCLUDED.

Written by J. F. McCLELLAND.

**CHUTES FOR DRAWING ORE FROM OLD STOPES**—The old mill holes in the mine stopes have caved in and are useless. For drawing the ore, chutes have been erected at intervals of about 25 feet along the drifts. These are peculiar in that they are put in after the regular drift timbering has been completed. The

a longitudinal section through a raise which was put up through an old stope to re-establish communication with some abandoned workings. The broken ore at this point was well packed in the stope and would not run in very large amounts. When the raise had been carried up about 50 feet a solid rock pillar was unexpectedly encountered, necessitating the change in direction shown in Fig. 19. The distance between the foot and hanging walls varied from 2 to 4 feet, and the walls themselves were fairly strong.

The timbering consists of three rows of short stulls (called spreaders) about 4 feet apart and set in hitches, as shown in Fig. 21. These divide the raise into two compartments, one of which is used for a manway and the other for an ore chute. Two-inch plank are spiked to the middle row of spreaders to form a tight partition between the compartments. Plank is also used for lagging the outside spreaders (Fig. 20).

Only one-half of the face of the raise is advanced at one time. The last spreaders on the other side are covered with planks, thus forming a roof, under the protection of which a man can stand and work. Most of the actual excavation is done with a bar, the loose material falling into the chute below. When the face has been advanced about 2 feet a couple of temporary spreaders (a, Fig. 20) are put in and cov-

co-operation of his partners or the men he employs to make his profit. He can rarely afford to add greatly to what appears to be a normal price for the work to cover changes in conditions which may occur.

## The Mines of Cripple Creek, Colo.\*

NUMBER III.

Written by W. LINDGREN and F. L. RANSOME.

**REPLACEMENT DEPOSITS IN GRANITE.**—The replacement deposits in granite all occur in close proximity to the contact with the breccia, and are well developed in the Elkton (Thompson), Ajax, Independence and Portland mines. Although these bodies of ore are related to fissures and occur particularly where several fissures intersect, or where they meet a dike, the ore is not confined to the actual fractures. The rock in the vicinity of these fissures is often extensively altered. The change from altered to unaltered rock, while never perfectly sharp, is often fairly abrupt and may take place within a distance of a few feet. The most obvious characteristic of the metamorphosed rock is a porous texture and a change of the reddish color of the normal granite to grayish or greenish tints. Closer examination shows that, while the porphyritic aggregates of pink microcline, so prominent in the Pikes Peak type of granite, may remain unaltered, the rest of the rock, consisting originally of microcline, oligoclase, quartz and biotite, may be completely recrystallized as a porous, vuggy aggregate of secondary orthoclase (valencianite), quartz, fluorite, pyrite, calaverite or sylvanite, and, in exceptional cases, sphalerite and galena. The ore minerals are partly inclosed in the other secondary minerals, but occur most abundantly with little projecting crystals of fluorite, quartz and valencianite on the walls of the irregular pores so characteristic of the altered rock. The biotite of the original granite yields most readily to alteration, and, in rock otherwise almost entirely unaltered, may be changed to an aggregate of fluorite, quartz and ore minerals. Some of the ore of the Ajax mine exhibits well this initial stage of alteration. With further alteration the original quartz and oligoclase of the granite are attacked. The quartz, originally in large homogeneous and irregular grains, recrystallizes as aggregates. Secondary orthoclase or valencianite forms often in clear, sharply idiomorphic crystals, which either project into open cavities or form aggregates with the secondary quartz. In many cases, however, the secondary valencianite results from the recrystallization of the older microcline practically in place. The two generations are sometimes distinguishable by the greater clearness and more or less idiomorphic form of the younger mineral and the absence of the characteristic microcline twinning. But it is often impossible to determine the line between feldspar which, from its association with quartz and fluorite, is clearly secondary and the original microcline of the granite. Occasionally a little calcite may be detected in the altered granite, but this is rare. The original apatite and zircon of the granite are not, so far as observed, affected by the alteration described.

While the replacement deposits in granite are important because of their size and the readiness with which the ore may be mined free from waste, the ore itself is usually of lower grade than that formed in the fissures of the sheeted zones.

**MINERALIZED "BASALT" DIKES.**—The ore bodies formed by the mineralization of basic dikes are in some ways closely related to the sheeted zones already described. Like the phonolite dikes, the "basalt" exhibits a pronounced tendency to split into thin sheets parallel with the dike walls. Normally, the minute fissures so formed are filled with veinlets of calcite and contain no ore. When, however, a zone of fissuring coincides with the dike the latter may be traversed by veinlets of quartz and fluorite carrying sylvanite or calaverite, while the body of the dike may be impregnated with pyrite. Such ore differs from that of the usual sheeted zones in breccia or phonolite in that the tellurides are not so clearly confined to the actual fissures, but appear to some extent to permeate the rock with the pyrite. The richest portion of the ore, however, undoubtedly occurs in the small veinlets in the dike, and usually near one or both walls where the fissuring is best developed. The occurrence of rich ore bodies in basic dikes in the Portland (Anna Lee), Moose, Elkton, Conundrum, Pinto and other mines has tended to exaggerate the importance of these dikes in general, and some have even supposed a genetic relation to exist between them and the mineralization of the district. Such an hypothesis, however, loses sight of the vast amount of profitless work that has been expended in the district in driving on the usually unproductive basaltic dikes, and the very small proportion of the known ore bodies that can be shown to have any connection whatever with these intrusions. That the basaltic dikes are not always readily mineralized even when accompanied by fissuring is shown in the interesting case of the Strong mine, where the ore occurs as mineralized granite on each side of the dike, while the latter is barren.

**DEPTH OF OXIDIZED ZONE.**—At a few points, as in

FIG. 16.

FIG. 17.

FIG. 18.

FIG. 19.

FIG. 20.

FIG. 21.

chutes are built between the sets, as shown in Figs. 15 and 16. When completed, three or four lagging poles directly overhead are either withdrawn or cut away.

The details of construction vary in different cases. Figs. 1 and 16 show a chute built under three-quarter sets, and Fig. 17 shows the form used with stull timbering. The gate is represented in section in Fig. 18. It is convenient and easily operated. The use of two gate boards gives good control over the passage of the ore and allows large rocks to be easily extracted. In order to facilitate the raising of the gate boards the front of the chute is made about 1 inch wider at the top than at the bottom (Fig. 16). Many of the chutes were erected and used to obtain large samples of the ore in the old stopes, while the property was being sampled.

**RAISING THROUGH AN OLD STOPE.**—Fig. 19 shows

ered with plank. The miner then stands under these and bars down the face on the other side of the raise. The permanent spreaders are put in when the raise has advanced far enough, and the lagging and partition are kept up as near as possible to the face.

This work is dangerous and requires a high degree of skill on the part of the miner. The ore in the chute was kept as low as possible, so that in case of a sudden cave of a large amount of material the chute would not fill up entirely and imprison the men.

In bidding on mining work by contract the miner usually bases his estimate on the appearance of the ground, and decides from experience about how much he can afford to do the work for and earn good day's wages. He makes a bid accordingly—adding to his estimate according to his knowledge of the men who are his competitors in bidding, but he relies largely upon hard work, full time, and the earnest

\*Abstract School of Mines Quarterly.

\*Abstract Bull. 254, U. S. G. S.

the Abe Lincoln and El Paso mines, tellurides are found almost at the surface. It is much more common, however, to find an upper zone, from 200 to 400 feet deep, in which free gold prevails and which gradually changes to the zone of pure telluride ores. As may be expected from the varying surface form and conditions of drainage, there is great range in the depth attained by oxidation. Partial oxidation extends in many mines to a depth of 1000 feet, especially along the often more or less open fissures. In the Wild Horse mine the zone of complete oxidation reaches a depth of 1100 feet and then suddenly ends. In the Isabella mine partial oxidation attained at least 1200 feet, and the same applies to the Gold Coin mine in Victor, although telluride ores prevail at that depth as well as in many levels above. The question is chiefly one of depth of ground water and of facilities for circulation of oxygen.

**RELATIONS OF ORE BODIES TO DEPTH.**—It is well known that the payable ores in auriferous lodes are rarely equally distributed in the lode, but form tabular bodies of more or less regular outline. The projections of these ore bodies on the plane of the lode often appear as elongated areas with greater vertical than horizontal extent. The ore bodies or shoots of Cripple Creek show great similarity to those of other gold-bearing veins; their limit in depth is usually as well defined as their extent in a horizontal direction.

Of sixty pay shoots of Cripple Creek mines plotted together for purposes of comparison, over thirty extended from the surface to a depth of less than 500 feet. The maximum individual production of these is less than \$1,000,000. Near six of these ore bodies further exploration developed new shoots below the old ones, but usually of smaller extent. In practically all thirty cases the development work had been carried down a few hundred feet below the best ore of the surface shoot. The form of these smaller shoots is often equidimensional; in a few cases the horizontal extent is greater than the vertical, or the shoot is wholly irregular; in many cases the shoot pitches steeply northward on the plane of the vein and the ratio of vertical to horizontal extent is 2:1 or 3:1.

In eight of the sixty cases the shoot extended from the surface to a depth of 1000 feet, or a little more, and ended. Further development to about 1500 feet failed to find new shoots of any importance, though small pockets are often discovered. In six of these eight cases the ratio of vertical to horizontal extent varies from 3:1 to 5:1, and the shoots usually pitch northward at angles of 60° to nearly 90° from the horizontal. In the remaining two cases the shoots have about the same horizontal as vertical extent. The maximum horizontal length is 1300 feet, while 400 is much more common. In two of the sixty cases the pay shoot is 1500 to 2000 feet long, maximum depths of 600 and 1000 feet having been attained and the bottom level being still in ore. In thirteen of the sixty cases the shoot began over 200 feet below the surface; in eight of these the bottom of the shoot has been reached, while in five the lowest level is still in ore. Steeply dipping, irregular elongated forms prevail. Many of this group of thirteen represent veins parallel and close to those on which pay shoots outcropping at the surface were found.

These statements will give an idea of the form of the shoots. Of course, in the case of shoots reaching the surface, a certain part has probably been removed by erosion. Judging from the shoots which distinctly began below the surface, the normal form of the ore bodies is elongated, vertical, or pitching sharply northward, the ratio of vertical to horizontal extension varying from 1½:1 to 5:1. Some of these shoots are, however, of about equal dimensions, vertically and horizontally, while in a few the horizontal dimensions are the greater.

Of the known ore bodies, as few exceed 1000 feet in length, so very few exceed 1000 feet in depth or extend more than 1000 feet from the surface. Speaking broadly, explorations below that limit have not proved very satisfactory. Drawing the lines a little closer, it may be said that in proportion to the amount of exploration the upper 700 or 800 feet have yielded more than the interval from that limit to the lowest levels reached—about 1500 feet. It must not be overlooked, however, that four or five mines still have good ore bodies at a depth of 1200 to 1400 feet from the surface. The developments of the next year or two will probably give a safer basis for generalization.

Roughly speaking, the above mentioned distribution holds good for any elevation within the district. In other words, the principal productive zone everywhere occupies the space from the surface down to about 1000 feet below it, and its lower limit thus forms a curved surface approximately parallel to the surface of the ground.

It is probable that the minimum depth of rock removed from the district by erosion amounts to 1000 feet in the central part and to 400 or 500 feet about the periphery. The shape and number of the ore bodies formerly existing in this eroded zone can be only conjectured. It is probable that the veins were formed shortly after the close of igneous activity, while the volcano yet possessed a much greater height than at present. The absence of hot waters and the depth of oxidation attained indicate that

vein formation at Cripple Creek is by no means a recent phenomenon.

The general features of the vertical distribution of the known ore bodies recorded above have of late years received more or less recognition, and there has been a decided tendency to attribute them to a process of secondary enrichment effected by waters moving generally downward from the surface. It has been supposed that such waters have carried down a part of the auriferous contents of those portions of the lodes now removed by erosion and have enriched originally lean pyritic ores by the secondary deposition of gold and silver tellurides and argentiferous tetrahedrite, with associated gangue minerals.

It is clear that the hypothesis in question is suggested by the distribution of known pay shoots. The question arises, How far does the distribution of known pay shoots represent the distribution of all the pay shoots in the district? In other words, How far has exploration been impartial in revealing ore bodies near the surface and at depths greater than 1000 feet?

It requires but little examination to make clear the fact that ore bodies within 1000 feet of the surface are far more likely to be discovered than those at greater depth. While shafts have been sunk for a few hundred feet without any indication of ore and have ultimately been developed into productive mines, such a procedure is considered bold prospecting, and few well-informed mining men would seriously contemplate sinking a shaft over 1000 feet in depth solely on the expectation of finding possible ore bodies below that depth. Most of the large mines in the district have started upon some indication of ore near the surface and have grown by the subsequent discovery of other lodes and ore bodies in the course of their underground development. As few individual ore bodies persist for more than 1000 feet in depth, by far the greater part of underground prospecting is at less depths, there being usually little inducement to go deeper, unless, as in the case of the Gold Coin and Portland mines, lodes are discovered in which the ore, beginning several hundred feet below the surface, extends deeper than the pay shoot upon which the mine was originally opened. Thus deep prospecting is usually confined to the vicinity of the larger and more persistent pay shoots which have been followed down from near the surface. Underground water has also proved a most serious obstacle to deep prospecting, few properties being able to develop below the 1000-foot zone unless there is abundant and high-grade ore in sight.

It may thus be concluded, without necessarily advocating promiscuous exploration below the 1000-foot zone, that any ore bodies existing below that depth are far less likely to be discovered than those above, where from the surface to depths of several hundred feet the rocks of the district are riddled with shafts, drifts, crosscuts and adits. It is exceedingly difficult, however, to determine, even approximately, the relative importance of this factor in this problem. It is probably safe to assume that the chances of discovering a given ore body within the 1000-foot zone are at least ten times those of discovering an ore

body in the Cripple Creek district has led to the conclusion that the fissures, which ordinarily are narrow and often appear as mere cracks, do become less abundant and less conspicuous at greater depth is attained. No mine exhibits this feature better than the Stratton's Independence, in which the very complex systems of productive fissures on the fifth and higher levels contrast more strikingly with the few, insignificant, and unproductive fractures visible on the fourteenth level. In less degree the same feature is shown in many other of the deep mines, but the rule is not without some very marked exceptions.

The dependence of the ore zone on the surface would then merely express the depth to which fissuring extended in a conical volcanic mountain.

We have thus two factors of importance to account for the scarcity of ore shoots below the 1000-foot level—first, difficulties of development and exploration, and second, the disappearance of fissures in depth. They do not seem to be sufficient, however, and it is believed that a third factor, as yet undiscovered, exists, and that it is related to the chemistry of the actual ore deposition.

In those districts where so-called secondary sulphide enrichment is known to have taken place, the ore minerals exhibit in general an orderly sequence, both in relative abundance and in kind, from those characteristic of the most highly enriched ore near the zone of oxidation to those constituting the original, lean and unaltered ore. The secondary minerals produced are such as can result from rearrangement and concentration of elements present in different combinations in the primary ores. At certain points within this range of alteration it is possible to detect direct mineralogical evidence of the change of one mineral to another, effected by solutions moving downward from the zone of oxidation. In most cases the secondarily enriched ores bear a recognizable relation to the lower limit of oxidation.

Careful study of the Cripple Creek ore deposits has failed to discover that the hypothesis of secondary enrichment is supported by crucial evidence of the kind just indicated. The minerals are not arranged in any discoverable definite sequence, nor does the present investigation find so much to support the view that the rich telluride ores, as a rule, pass with increasing depth into low-grade pyritic ores. Frequently such ore as occurs below a depth of 1000 feet is precisely the same in character as ore found within 100 feet of the surface. Tetrahedrite, which has been regarded by some (without definite proof) as a secondary mineral, occurs sporadically throughout the district and at all depths reached by present workings. The richest ore does not uniformly occur immediately below the oxidized ore.

### Unique Water Wheel Connection.

The Hercules M. Co., Harry Day manager, at Burke, Idaho, has installed water wheels to be used in connection with their mining operations in the

Unique Water Wheel Connection.

body below that zone, and the ratio may be very much greater. It is probably true that there was originally more ore within the 1000-foot zone than there is in a corresponding zone below, but this disparity is not necessarily anything like so great as is indicated by the vertical distribution of known pay shoots.

Another important line of inquiry bearing upon the relations of ore bodies to depth is concerned with the question of the relative size and abundance of the fissures near the surface and at greater depth. It has been shown that all the ore bodies are intimately connected with fissures. If such fissures are generally smaller and less abundant below the 1000-foot zone than they are within it, obviously there is introduced a factor which diminishes the supposed importance of secondary enrichment by affording an anterior and physical explanation for the decrease of ore with increase of depth.

Detailed examination of practically all the access-

to the Hercules M. Co., Harry Day manager, at Burke, Idaho, has installed water wheels to be used in connection with their mining operations in the

### Gold Mining in Rhodesia.\*

Written for the MINING AND SCIENTIFIC PRESS by F. C. ROBERTS.

Lying between latitudes 16 and 23 south, and longitudes 25 and 30 east, Rhodesia, which a few years ago was (with the exception of a few missionaries and a stray hunter or two) almost wholly inhabited by the native tribes, can now boast of a white population of about 10,000, which, with the exception of those resident in the two centers, viz: Bulawayo, about 4000 population, and Salisbury, about 1200 population, go to make up several fair sized mining camps.

The country derives its name from the founder, the late Right Hon. Cecil John Rhodes.

In its physical aspects, Rhodesia differs somewhat from most of the Western mining States, in that few if any really high mountain ranges traverse the country. The mining districts embrace, in the broken areas, numerous small hills which gradually fade away into large areas of first undulating and then almost flat plains.

In the granitic belts quite an independent type of scenery is presented, consisting of large slightly undulating plains, dotted with countless small, conical shaped hills (kopjes) varying in height from 50 to 300 feet.

In but one instance in the whole of Rhodesia has it been found advantageous to attack the ore bodies and veins through adits or crosscuts, practically every mine in the country, if not originally, has eventually been opened up through vertical or inclined shafts.

The gold mining industry is at present the only industrial source of revenue which the country can boast of, and in its commercial aspects is very difficult of comparison with those existing in other countries, as the local conditions obtaining here are peculiar to Rhodesia alone. The vicissitudes to which the country has been subjected have been numerous, unique and costly, and have militated against and deflected seriously the energy and enterprise which would have been thrown into the country, and the progress which would have been made, has in consequence been greatly hindered.

One really wonders how the present position has been attained, and what has been the source of the large sums of money which have been invested in the country.

The internal system of railways, which are being extended throughout the country, are calculated to bring within easy access of the centers (Bulawayo in Matabeleland and Salisbury in Mashonaland) practically every mining district of importance, many of which have been seriously affected by reason of the

Falls) is nearing completion, and it is anticipated that within the next few months the coal being mined at the Wankies fields will become available for use in practically all of these mining districts. In some cases coal will shortly be an absolute necessity, in

as mineralogical, problems, which promise to be of especial interest and importance, and fortunately, in both instances the auriferous nature of the occurrence warrant the extension of exploratory work, and petrographical knowledge will thus be obtained

Quartz Mill in Rhodesia, S. A., Showing Manner of Arrangement.

almost prohibitive prices and scarcity of wagon transport.

An independent line, called the "Wankies" line, about 200 miles in length (really the first link in the Cape to Cairo Railway, from Bulawayo via Victoria

others wood fuel will for a few years be the more economical.

**GEOLOGY.**—Geologically, those sections of Rhodesia which have been favored with sufficient exploitation to allow of intelligent research, present more or less the same interesting field as other quartz countries. Perhaps we are favored here with geological, as well

which might otherwise be entirely confined to theory. I refer to an auriferous diorite in one case and a gold-bearing hornblende porphyrite in the other.

A geological survey has not yet been extended in Rhodesia, hence but transient reference will be made to the rock series. By far the greater areas include the granitic rocks, these forming extensive zonal

\* See illustration on front page.

belts, having a general strike somewhat west of north and east of south. The mineralized belts embrace those sections containing the slates and schists, which strike in every direction, including areas varying from a few hundred yards wide by half a dozen miles in length, to 15 miles wide by 30 miles long.

These metamorphic rocks are traversed by numerous dikes, embracing chiefly the many varieties of diorite. In the valleys or small gulches existing in the hilly districts the alluvium is of very limited extent, suggesting a lack of these extreme climatic conditions which induce rapid erosion.

The quartz veins met with include several distinct types, probably the most common being the inter-laminated veins, which are found abundantly in the foliated rocks, while in most districts many segregated veins occur. The quartz exists, generally speaking, in more or less lenticular bodies, sometimes showing distinct isolations, and often found in parallel series, exhibiting great variations in width, both laterally and vertically. Speaking generally, the veins are of small width, and the lateral extent is not great.

At the Ayrshire mine, situated in the district of Lomagundi, Mashonaland, an auriferous diorite is under exploitation, but as yet the genesis of the gold occurrence is not clearly understood. A large amount of work has been accomplished laterally and the vertical depth reached is something over 600 feet. The irregularity of the gold contents of this dike, combined with various other characteristics, would seem to support the lateral secretion theory. It is to be hoped that, from time to time, accounts will be published touching the determinations made during the exploitation of this most interesting property.

complicated and the quantity of gold, copper and iron extracted by them must have been enormous.

While the remains of these old workings have largely aided the prospector, during the early history of the country, when conditions were more or less abnormal, there is little doubt but that the influence has been an injurious one, and has not assisted in the introduction of a thorough system of prospecting, and has, in a great measure, deflected attention from the large areas containing virgin reefs, which were probably not uncovered at the time the work was in progress.

Several calculations have been made touching the amount of gold extracted by these ancients. These estimates are entirely hypothetical and no accuracy is claimed for them, but the latest calculation reaches \$300,700,000.

The value of a mining proposition is measured by the extent of these old workings laterally and vertically, and the resulting disregard of the geological considerations has, no doubt, been directly responsible for the early failure of a number of mines.

The knowledge displayed by these ancients in the determination of the value of the ore was indeed marvelous. It is, of course, not to be assumed that they valued the important factor "width of vein," but it would appear to have been sufficient encouragement to them that a vein contained, say, a minimum value of 10 dwts. per ton. This work was no doubt extended over a very great period, for in instances where the rock had not lent itself readily to oxidation, they built fires in the stope breasts and then cast water upon the heated rock preparatory to breaking down.

In some instances where it is evident from the contours, that water difficulties were not met, they

while the seams of the drums are located at the top, away from the fire. The throat is braced with a twisted brace which leaves over 80% of the area open. The rear drum contains a mud pau through which the feed water flows, and where practically all the impurities of the water are precipitated to the bottom of this pan, from which a connection through the drum head admits of its being blown out. This mud pan or purifier is built in sections and can be removed through the manhole of the drum. The mud pan occupies small space and there is considerable generating surface in this rear drum. The fresh water from the purifier flows down through the rear leg and up through the tubes and front leg to the front drums, where there is a large releasing surface. The two drums are connected by straight equalizing tubes, arranged in three tiers along the ordinary water line. Each of these drums is connected with a middle drum by tubes and the steam, as it is released, travels through these tubes to the middle drum, from which it is taken for use. Experience has shown that, by thus carrying the steam to a third drum through tubes exposed to the furnace gases, not only is perfectly dry steam obtained, but this steam is given superheat varying from 10° to 22°, according to the state of the fire. Since all the tubes carrying water are straight and readily accessible, the boiler is easily cleaned.

### Unwatering the Comstock Lode.\*

For years numerous efforts have been made to unwater and explore the entire Comstock lode. The latest arrangement in this direction has recently been made by the Ward Shaft Association, consisting of a group of the middle mines, composed of Gould & Curry, Savage, Chollar, Potosi, Bullion, Alpha Consolidated, Exchequer, and the Julia Consolidated M. Co., who own and operate nearly a mile of the middle lode. This association, through its chief engineer, Leon M. Hall, who is also superintendent of the Ward Shaft Association, has awarded an important contract for a permanent pumping installation to the International Steam Pump Co. of New York.

It is now about twenty-six years since the largest pumps were installed in these mines, of the steam actuated type; since then science has progressed in the development of pumping appliances. The development and responsibility of successfully demonstrating that the later types of pumps will accomplish the exploring of the southern portion below the 2500-foot level has fallen on the shoulders of Leon M. Hall, chief engineer and superintendent. The northern half has already reached a depth of 3000 feet with good returns from the deepest parts. There are known to be mineralized bodies below the 2500-foot level in the middle and southern parts, where the inrush of water about twenty years ago flooded all the middle mines up to the 1600-foot Sutro tunnel level. All these levels have been idle, and it is Mr. Hall's belief that it is possible to unwater, ventilate and successfully and safely work the levels as deep as 5000 feet.

The water that was met twenty years ago on the 2900-foot level of Exchequer mine in Gold Hill was 170° F., and the temperature of station and workings about 110° F. After various efforts to handle the inrush of water it was finally decided to allow the water to fill to the Sutro tunnel. About ten years ago another effort was made to unwater the mines through Crown Point incline, which also was abandoned after an expenditure of about half a million dollars, and future workings were confined to the 1500 foot level.

At this time hydraulic pumping engines were installed together with various Cornish engines, all of a capacity to keep the water at 3300-foot level in the north mines, but the expense of operating was so great that the mines were allowed to fill up to the 1600-foot level and workings were confined to the more accessible ore bodies above Sutro tunnel. The fact that the character of deposits which were worked at higher levels will continue at the lower levels has induced the mining companies to make considerable effort to reach them; about four years ago a large hydraulic lift was installed at the Consolidated California shaft, and with this appliance the water level in the north end has been kept below Sutro tunnel about 2150 feet, and considerable amount of valuable ore has been taken out, amounting to over \$1,000,000. Having reached this level, another effort was made to go lower, installing an electric pumping plant consisting of three Reidler electric pumping engines driven by a 200 H. P. induction motor for each. These pumps take the water at the 2150-foot level and together discharge 4500 gallons per minute into the Sutro tunnel under 430-foot head. The hydraulic pumping engine serves as a sinking pump, discharging into tank at the Reidler pump.

The electric power is generated by the Truckee river, 2 miles east of Floriston, Cal. McCormick turbines are directly connected to Westinghouse three-phase generators of the revolving armature type. Each pair of wheels will develop about 1400 H. P. under head of 84½ feet. Regulation is effected through

\* See illustration on front page.

Modern Mine Equipment in Rhodesia, S. A.

The writer recently discovered an auriferous hornblende porphyrite. This rock is a most interesting one, petrographically, and is quite uncommon in this country. It consists, as seen under the microscope, of large crystals of feldspar (chiefly plagioclase), possibly with some orthoclase, and smaller calcareous pseudomorphs after hornblende, retaining good crystal outline, imbedded in a fine-grained feldspathic groundmass. The feldspars are somewhat crushed, and the alteration of the hornblende implies a certain amount of water action. This body has recently been the subject of exploitation and appears to predominate in the moulding of a small range of hills rising some 500 feet above the surrounding country. In close proximity to the porphyrite are the crystalline schists.

A superficial examination of the body shows considerable variation in width, the probable extreme being about 150 feet, while the lateral extent appears to extend for a distance of 1000 feet or more. Enough work has not yet been accomplished to enable one to make very thorough determinations respecting the geology, nor can an intelligent idea as yet be expressed with regard to the origin of the gold contents.

Samples taken over the various widths exposed return from 2 dwts. to 15 dwts. per ton, and although these results are not representative, they show the body to be of sufficient importance to suggest the production of some quite unique, if not valuable, conclusions.

ANCIENT WORKINGS.—An interesting feature in connection with the mineral industry of Rhodesia is the fact that every auriferous district in the country has been largely worked by an extinct race of people, popularly referred to as the ancients; and although some relics left by these people have been found in the bottom of old stopes, lately opened, and also about the numerous ancient ruins existing in the country, no tangible idea has yet been advanced touching their identity. The amount of work ac-

worked to a depth of no less than 250 feet on the reef plane.

Most of the producing mines in the country, as well as those upon which a goodly quantity of development is being extended, are marked by extensive old workings.

(TO BE CONTINUED.)

### The Atlas Water Tube Boiler.

The Atlas Engine Works of Indianapolis, Ind., has sold a number of water tube boilers for the use of the

Atlas Water Tube Boiler.

Japanese Government in reconstructing the dock machinery at Port Arthur. This boiler is composed of a nest of tubes, set on the ordinary incline between water legs, and three drums running across the tubes instead of lengthwise at the top. Two of these drums, the front and rear, are each a part of the same plate composing the water leg, with which it is connected. This eliminates seams next to the fire or hot gases, since the only seam in each of these legs is at the bottom, where it is protected by the masonry,

Lombard governors. The generating potential of 500 volts is raised to 24,000 volts by Westinghouse oil insulated transformer. The current is transmitted about 35 miles to Virginia City, Nev., over a double circuit of copper wire. The mining companies purchase power from the Truckee River General Electric Co., the amount used being based upon peak load to two minutes duration when the electric hoists are operated directly upon the lines; price, \$7 per H. P. per month. There are about 2000 H. P. installations on the Comstock Lode, to be increased to nearly 5000 H. P., a contract having been closed between the Truckee River General Electric Co. and the thirty-two mining companies comprising the Comstock Pumping Association, which calls for delivery of electric power draining the Comstock mines, lighting, hoisting, etc., the maximum amount being 5000 H. P. To fill these contracts for additional power, the Truckee River Co. has prepared plans for a second electric generating station and a new pole line. Water will be diverted from the Truckee river and conducted to the extreme eastern end of the company's hydraulic system, where it will be utilized by water wheels under head of 41 feet. For the maximum of 5000 H. P. the rate will be \$4.50 per H. P. per month, with proportional rates for lesser amounts. This is based on motor readings and will save the mining companies considerable money as compared with the existing contract. All motors of 50 H. P. and over are operated directly on 2240 volts, all smaller motors on 440 volts, and the lighting circuit is 220 volts, three-wire system, except Gould & Curry, which is on 110 volts.

The ventilation in the mines is of the best, as it must be, owing to the excessive heat and saturation from hot water. Most of the ventilation is of the natural type through various shafts on the different levels. The cold air is forced by electric fans to the different headings and stations. The electric hoisting engines are of Mr. Hall's design, he adopting the balanced or tail-rope system of hoisting.

The Reidler pumps were put in at the C. & C. shaft in 1902, because of inability of going any farther than 450 feet below Sutro tunnel level with the power from the hydraulic water supply for the hydraulic elevators. It proved a practical sinking pump; cost of repairs small. The Reidler electric pumping plant handles the mine water and also pressure water when the hydraulic elevators are used for sinking. When the shaft is free from water, another pumping plant will be placed at the 2550-foot level and the use of the hydraulic elevators will be abandoned.

In determining the types and designs for the Ward shaft the association were able to select the plant from the best type of pumping machinery in the world, considering the electric motor and pumping engine as a whole unit. Motors designed for such slow speed as 100 revolutions of such large capacity will give a low power factor; one of same capacity running 200 revolutions should give 15% to 20% better results, which means the amount of power saved at the generating station and less cost for operating, and on this basis high speed 200-revolution pumps without mechanically operated valves were selected.

The International Steam Pump Co. was represented by Charles C. Moore & Co., Engineers, its Pacific coast agents; its chief engineer, C. G. P. de Laval, who went to Virginia City to investigate the situation; Leon M. Hall, chief engineer and superintendent for the Ward Shaft Association, conducting negotiations for this association.

The contract calls for two first-motion electrically driven pumps, each of the units to have a capacity for lifting 1600 gallons of water per minute against a pressure equivalent to a height of 1500 feet, or from the 3000-foot level up to the level of the south lateral branch of Sutro tunnel. Each pump is to be driven by 800 H. P. slow-speed induction motor. The contract includes column pipe, travelling crane for the pumping station, automatic oil system, small air compressor for filling air chambers, a small vacuum pump operated by compressed air for discharging air from the suction chamber, all the piping and valves of every description for completing the installation and a complete set of duplicate parts of the pump.

It is intended to install a temporary drainage plant at the Ward shaft, first using an air lift to lower water to the 1800-foot level and thence down to the 2500-foot level with other pumps. The present bottom of the shaft is at the 2500-foot level, and when that point is reached the shaft will be sunk through the solid rock to the 3000-foot level, where the permanent pumps contracted for will be installed.

A descriptive cut of similar type of pump is shown herewith, which embodies all the details of the ones for the Ward shaft. Pumps of this type are built in capacities from 200 to 4000 gallons per minute and for heads from 100 to 2000 feet. Speed of pumps in the accompanying installation is 300 revolutions per minute, efficiency of pump alone is stated to be 95%, motor 92%, combined efficiency 85%. The entire machine is self-contained, mounted on a rigid box girder frame and occupies a relatively small space. It contains some novel features of construction and careful attention has been given to the design of the internal portion as well as to the running parts and oil devices. Its operation is practically noiseless under all conditions and unaccompanied by shock or heating. The weight of both pumps for the Ward shaft and their motors is about 600,000 pounds, which may

be interesting for comparison with the older pumps on the Comstock.

The Ward shaft electric pumps will have capacity of 3200 gallons against 1500-foot head and cost \$80,000. The Mexican-Union pumping engine was a Cornish type compound condensing, flywheel, Leavitt arrangement of cylinders, flywheel 36 feet in diameter, which flywheel with its shaft alone weighed 208,700 pounds; high-pressure cylinder, 64 inches diameter by 6 feet 9 inches stroke; low-pressure cylinder, 100 inches diameter, 8 feet 6 inches stroke; nominal stroke of pump 10 feet. This engine was constructed in 1880 with a double line of 14-inch plunger pumps, discharging into Sutro tunnel. Later the 14-inch pumps were replaced by 17-inch and additional 18-inch pump rods were added about 1000 feet long. The pump rods from top bob to the 2700-foot level were 2618 feet long. The total weight of moving parts was 1,620,500 pounds; total lift of water 1180 feet to Sutro tunnel from 2700-foot level station. Due to the great length of pump rods, the effective stroke of plungers was reduced from the surface stroke of 10 feet to actual stroke of 9.7 feet.

The Chollar, Norcross, Savage, Belcher and Overman were all of the compound vertical condensing engine, Davey type; high-pressure cylinders, 32 inches in diameter, stroke 10 feet 9 inches; low-pressure cylinders, 65 inches diameter, 8-foot stroke. No flywheels are used on this type and strokes are variable as in any direct-acting pumping engine. These pumps force water from 3180-foot level to Sutro tunnel, 1570 feet; total weight of moving parts 1,374,900 pounds.

In the underground station cuts at 2400, 2600 and 3000-foot levels hydraulic pumping engines were used. The ratio of power plungers to pump plungers was proportioned so pumps could make six to seven strokes per minute.

In the Yellow Jacket shaft a pump was installed in 1880 which was considered of superior efficiency. The type of engine twenty-five years ago was horizontal compound flywheel design, high-pressure cylinder, 31 inches in diameter; low-pressure cylinder, 62 inches in diameter; stroke, 12 feet. The balance bob was so constructed that pump cylinders would receive 10-foot stroke. This pumping engine took the water from the 3000-foot level, pumping same direct to the surface, having total length of pump rods of 3055 feet; weight of the moving parts, 1,510,400 pounds; engine made 5½ revolutions when 432 gallons capacity. An accident occurred to this engine closing it down until the Sutro tunnel was completed, when it was changed by a double line of pumps raising the water 1516 feet to Sutro tunnel and pumping 700 gallons per minute. A month later a heavy flow of water from the 2700-foot level of Exchequer mine was met, flooding all the lower levels. Pumps were speeded up to their utmost capacity, 750 gallons per minute, but the waters were still increasing and pumps were not able to hold it, nor could any other means at hand control the water. It was then stopped entirely.

In the Ophir mine the horizontal-gear type of engines was used, steam cylinder, 24 inches in diameter, 5-foot stroke and fitted with two flywheels; pump stroke was at surface 8 feet and 7.7 feet below; total length of pump rods (partly on the incline), 3273 feet; weight of moving parts, 1,067,500 pounds; water pumped 900 feet to Sutro tunnel discharging 280 gallons per minute.

At the Con. California shaft the engine was of the Davey differential type, high-pressure cylinder 24 inches in diameter, low-pressure cylinder 40 inches in diameter, 8-foot stroke, with 7-foot stroke for pumps. Pumps could furnish 500 gallons per minute; and weight of moving parts 860,000 pounds, with 2150-foot length of pump rods. These pumping engines cost, without foundations and installation, \$1,300,000, giving maximum capacity for all of 5400 gallons to an average height of 1152 feet; average cost for operating, about \$34 per indicated horse power per month; total amount of water pumped, 5040 gallons, to an average head of 1074 feet, with a total indicated H. P. of 1703. Total cost per month, \$58,120, or \$697,440 per year, not including repairs. The hydraulic pumps handled 2128 gallons per minute and the Cornish 2912 gallons, requiring about 2.7 miles of rods, which, together with other moving parts, made a total of 6,496,400 pounds of reciprocating details requiring same to be started and stopped nine times every minute, thus requiring 2330 pounds of moving parts for every gallon pumped.

These figures are given as comparison between modern high speed engines with small parts and light weight, as there is no heavy moving in direct-connected pumping engines, and gives at once the most flexible system, accommodating itself to any size installation. Great weights in motion limit speed, and material stresses are soon overreached, causing breakdowns and repairs. The old Comstock pumps

could not be increased in capacity, as extra weight brought reduction of speed, which was experimented on at the Mexican Union, where speed had to be reduced to about four revolutions per minute on account of overstraining rods, which were 18x18 inches Oregon pine and 2618 feet in length. Owing to the extreme hot water (170° F.) and high temperature of shafts, the machinery and parts had to be constantly lubricated to an excessive extent, requiring careful watching for rotting of pump rods, rusting of wrought parts and destruction. The cost of maintenance and power was enormous and could not continue with the advent of new methods and devices, with the demands of shareholders for more dividends, and newer and better types of machines were looked for, and when the C. & C. electric pumps were started a new era dawned upon the Comstock Lode. Permanent Knowles electric express pumping engines, just contracted for, will drain the group of the middle mines upon the Comstock Lode to a depth of 3000 feet through the Ward shaft.

The greatest depth ever attained on the Comstock was in the north end, in the Union Con.—3350 feet—in 1883; the present stated ability and intent to go 5000 feet indicates possibility of producing further great addition to the enormous amount already yielded.

The Comstock Lode was first discovered as a gold mine, although the subsequent discovery of sulphurets of silver among the gold eventually made it the first silver mine in the United States. But it was not until the fifth year that silver predominated over the gold, the yield for that year being: Gold, \$4,940,000; silver, \$7,460,000; total, \$12,400,000. Its greatest product in any one year was during the bonanza days of 1877, which recorded a yield of: Gold, \$14,520,614.68; silver, \$21,780,922.02; total, \$36,301,536.70. This is taken from the official Government report, Treasury Department, Washington. Afterward gold again predominated, the yield for 1885 being: Gold, \$1,729,531.25; silver, \$1,415,071.04; total, \$3,144,602.29. Gold has continued to predominate each year since. The total yield of the Comstock to date is about \$379,000,000, over \$20,000,000 being silver.

### Challenge Ore Feeder.

Herewith is illustrated the Challenge ore feeder, in which the ore is delivered by a hopper on to a disc inclined slightly from the horizontal, supported and rotated by a spindle keyed at right angles to the center of its face, the spindle journaled in boxes on the front face of the hopper, one-half the disc projecting beyond the hopper. The ore rests on approximately one-quarter of the disc inside the hopper, and, as the disc is rotated, is carried out through an opening in the front of the hopper; this opening, 12 inches wide, permits feeding coarse material, and an adjustable gate which is fitted across it, prevents the weight of ore in the hopper from forcing the ore ahead any faster than it is fed by the rotation of the disc. A guide wing encircles the outer projecting edge of the disc, thus preventing any ore from falling off the disc until the point of feed is reached; a

Challenge Ore Feeder.

cast iron scraper wing crowds the ore ahead as the disc is rotated, thus causing ore to be delivered through the feed opening, 15 inches wide.

In this feeder any lost motion is automatically taken up. The amount of feed can be adjusted while the feeder is in operation, the hand wheels governing this being within easy reach from the floor back of the mortar. The clutch mechanism is enclosed in a dust-proof casing, equipped with oil cups.

This feeder is furnished either stamp or belt driven, and equipped either with bracket hangers or rollers and track, as desired; it is manufactured by Colorado Iron Works Co., Denver, Colo.; its shipping weight is about 1000 pounds.

# Mining and Metallurgical Patents.

PATENTS ISSUED JANUARY 24, 1905.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS

PROCESS OF SEPARATING GRAPHITE FROM WOLLASTONITE.—No. 780,297; S. R. Krom, Plainfield, and S. V. Krom, Jersey City, N. J.

Process for separating graphite from ores carrying same, consisting in crushing ore to fine granular condition, separating major portion of graphite from ore by dry concentration, treating concentrates or residue in bath of dilute sulphuric acid so as to break chemical bond or union of materials treated and thereafter submitting decomposed mixture to concentrating washing for recovery of graphite.

DROP BOTTOM DUMP CAR.—No. 780,762; S. Otis, Chicago, Ill.

In drop-bottom dump car, combination of supporting framework, and drop bottom therefor formed of plurality of swinging sections having independently movable rear and front portions pivotally secured in position to each side of longitudinal center of car, substantially as described.

EXCAVATING MACHINE.—No. 780,686; L. Rosebush, West Bay City, Mich.

In combination with traction engine, platform secured to front end thereof; hoisting drum mounted

on platform; devices for operating drum from engine: cross beams supporting platform; forwardly and outwardly extending legs pivotally suspended from beams; upwardly and outwardly extending arms pivotally secured to each side of platform; inclined shear legs pivoted at upper ends to arms; runners pivoted lower ends of shear legs; hoisting block secured to each of shear legs; cables oppositely wound on drum and extending respectively through each of hoisting blocks; and scrapers secured to ends of cables.

PROCESS OF SEPARATING METALS FROM THEIR ORES.—No. 780,651; J. M. A. Gerard, Paris, France.

Process of producing metals from ores, consisting in heating mixture of ore, flux and carbonaceous material to reduce ore to metal sponge, passing through resulting product electric current to melt same, separating slag from metal, and subjecting fluid metal to action of electric current of high voltage and low amperage in presence of oxidizing gas, whereby metal is made to boil and rapid oxidation is effected.

AMALGAMATOR.—No. 780,529; J. B. Rossman, St. Paul, Minn.

Amalgamator bowl having circular concave bottom, rubbers pivotally mounted within bowl and means for imparting to rubbers oscillatory motion about its center and over segment of bottom, whereby successive areas of agitated and dead water are produced within bowl when in operation.

MAGNETIC SEPARATOR FOR ORES OR SIMILAR MATERIALS.—No. 780,870; J. T. Dawes, Liverpool, England.

In magnetic separator combination of moving conveyor for receiving material second moving conveyor above first moving conveyor, magnet pole above second moving conveyor, and shield disposed under second moving conveyor between outer extremity of magnet pole and first moving conveyor and parallel to and in contact with side of first moving conveyor, part of top of shield under magnet pole being level with first moving conveyor.

MERCURY FEEDER FOR STAMP BATTERIES, ETC.—No. 780,493; N. P. Carver, Edgecliffe, near Sydney, New South Wales.

In device of class described, combination of trough adapted to contain liquid, member rotatably mounted above trough, bucket pivotally mounted on member, eccentrically of same, bucket having peripherally disposed lifting compartment and radially disposed

measuring compartment communicating with each other, guide for causing bucket to rotate on its pivotal axis through rotation of member for raising liquid from trough by means of lifting compartment, then causing liquid to flow into measuring compartment and finally discharging contents of measuring compartment over edge of trough.

METHOD OF AGGLOMERATING MAGNETIC ORE.—No. 780,716; Elmer Gates, Chevy Chase, Md.

Method of agglomerating magnetic sand, which consists in establishing electric arc between opposing surfaces, feeding opposing streams of sand over surfaces, and causing streams of sand to fall freely from surfaces so as to break arc originally formed and establish arcing from one of falling streams to other, thereby fusing and agglomerating sand into small lumps of size varying from that of wheat grain to that of bean.

MINING BUCKET DUMPING APPARATUS.—No. 780,629; W. R. Wilcox, Boise, Idaho.

In apparatus of class described, combination with shaft opening or like, of closure therefor, bucket movable in line of opening, dumping mechanism interposable in path of bucket, mechanism including bridle flexibly suspended from point in advance of bucket and adapted to have movement in horizontal direction to intercept bucket, and unitary means for opening and closing closure and operating dumping mechanism.

## THE PROSPECTOR.

The rock specimen from Blackbird, Idaho, is apparently a diorite aphanite, that is, a dense fine-grained diorite. It contains a large percentage of pyrrhotite, a subsulphide of iron, slightly magnetic. Nickel is often found associated with pyrrhotite and this ore should be tested for nickel.

The rock specimens from Liscum, Ariz., are a granular quartz rock in which is disseminated a quantity of specular or micaceous iron—a variety of hematite.

The rocks from F. R. J., at Northport, Wash., are as follows: No. 1 is a foliated graphitic slate containing veinlets of calcite and quartz; in the quartz are a few small crystals of pyrite, possibly gold bearing; a little pyrrhotite is also present. No. 2 is vein quartz, apparently formed in a country rock, like No. 1; it contains a little iron sulphide and may contain gold. No. 3 is a slaty rock in which occurs a large amount of pyrrhotite and a small amount of iron sulphide.

The soft, white rock from Tombstone, Ariz., marked 1. A., is kaolinized feldspar, probably an altered eruptive rock like diorite or granite, containing chalcopryite (copper sulphide), altering to bornite, also a copper sulphide. Ore similar to this is more or less abundant at the Cananea, Mexico, copper mines.

The rock samples from Tombstone, Ariz., may be described as follows: The lighter colored rock is a dense siliceous rock and is probably altered shale or limestone. It has been fractured by pressure and movement and in it occur numerous little veins of quartz. Galena is seen in groups of small crystals scattered through the mass. The dark colored rock is amygdaloidal lava containing numerous zeolites in a more or less advanced stage of decomposition.

## MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

### ALASKA.

The Continental Investment Co., at Windham Bay, has put in an air compressor and will drive a crosscut to tap a ledge shown by surface croppings.—F. Freming, working claims adjoining the Jualin mine at Berners bay, has struck the ledge.—The Greek Boys at Berners bay has been sold to an English company who will build a mill.

The Oceanic M. Co. is putting in a compressor at Sum-dum which will be used in sinking two shafts on the Sunnyside claims. Superintendent Ahrenstad has sunk one of these shafts 150 feet and the other 25 feet.

It is reported that the Ebner G. M. Co., working near Juneau, will build a 100-stamp mill. The present 15-stamp mill is running with water power.—The 300-stamp mill of the Treadwell Co. closed down on the 5th ult., after running continuously with water power, with the exception of seven and a half days, since last April—over nine months. This mill treats an average of five tons of rock per stamp every twenty-four hours, which is equivalent to 1500 tons per day.—All the mines at Treadwell are said to be yielding increased values with increase of depth. The Treadwell main shaft is now down 1000, the Mexican 1200 and the Ready Bullion 1300 feet.

### ARIZONA.

#### Cochise County.

(Special Correspondence).—The smelter at the Copper Queen at Douglas recently produced 163 tons of bullion in twenty-four hours.

Bisbee, Jan. 30.

#### Gila County.

(Special Correspondence).—The Globe M. Co. of Globe held its second annual meeting in Chicago and elected J. F. Hechtman of Globe president and manager and J. Goodwin of Globe and S. J. Collins of Moline, Ill., as directors. Sinking will be resumed on the main shaft and the Vacy Constance will be developed. The country rocks are granite, porphyry, quartzite, diorite and syenite, showing fissure veins in the diorite from 2 to 100 feet in width, with iron cappings. The ore carries copper, silver and gold. C. J. Maybush is mine superintendent. Globe, Jan. 30.

#### Graham County.

(Special Correspondence).—The recent floods destroyed the dam at the camp of the Detroit Copper Co., near Morenci. The dam was constructed to conserve the tailings and slimes from the company's plant. It is being repaired and strengthened so that it will be better able to resist any water pressure that may come against it in the future. Several improvements have been made for handling the tailings, and it is expected that the dam will not again be washed away so easily. This mine was opened in 1880 and worked open cast, as the ore bodies are of great size, though low in grade. The ores are chiefly sulphide and highly siliceous, with gangue carrying up to 40% alumina, requiring careful handling. The concentrating ore is about one-half oxides and carbonates and one-half sulphides. The ore is concentrated seven into one, using 400 gallons of water per ton of ore. Eighteen hundred gallons of water are in constant use, 125 gallons per minute of clear water being supplemented by clarified water from settling ponds and clarifiers designed by G. E. Hunt, mill superintendent. The fresh water is pumped from wells on the San Francisco river.

Morenci, Jan. 30.

#### Maricopa County.

(Special Correspondence).—J. Hauxhurst will increase the force at work on his copper property near Wood-chopper's Tanks in the Osborn district.—The Gila Gold Lode Co. are working a gold property 35 miles west of Phoenix.—A. L. Crenshaw will put machinery on his property in the Cave Creek district.—The Oriental M. & M. Co., operating in the Cave Creek district, will resume operations.

Phoenix, Jan. 30.

#### Mohave County.

C. D. Pickering, superintendent of the Yucca Cyanide M. & M. Co. at Cedar, reports the 10-stamp mill is to be remodeled and the ores worked.

W. F. Grounds of Fresno, Cal., owner of the Clay Springs mines, 22 miles north of Hackberry, has put in a 4-stamp mill 2 miles from the mines and the water piped 4 miles from Clay Springs. The mill will be started Feb. 1st.

#### Pima County.

(Special Correspondence).—The Twin Buttes Co., near Tucson, has struck a body of ore in the double compartment shaft. The ore carries copper, silver and lead. Tucson, Jan. 30.

#### Pinal County.

(Special Correspondence).—Oil has been found at Mammoth after drilling 600 feet; the well is to be continued till 1000 feet is reached. This is said to be the first find of oil in Arizona.

Mammoth, Jan. 30.

(Special Correspondence).—The Troy-Manhattan smelter at Riverside has made a successful run of ten days, but owing to the severe storms, which washed out numerous bridges on the Phoenix & Eastern Railroad, was compelled to shut down pending the arrival of supplies of fuel oil and coke which is held up on the railroad. The steam hoist has been removed from the Ninety One shaft to the main shaft and is now in commission. The boiler from the Alice shaft has also been removed to the main shaft, and with others to be placed with it, there will be a battery of four. A body of high-grade copper ore 20 feet in width has been opened in the Buckeye mine. The new double compartment shaft on

this property is now down 206 feet, and a large area of stoping ground has been opened.

Troy, Jan. 31.

#### Yavapai County.

(Special Correspondence).—Douglas Lacey & Co. of New York have a bond on the Iron King Extension claims No. 1 and No. 2, near the Iron King property, in the Big Bug district. They have been in litigation for a number of years, which was finally settled in favor of A. J. Carroll, who gives the bond. On one of the claims there is a crosscut 205 feet long.

Prescott, Jan. 31.

The Easy Boss mine, 2½ miles from Mayer, is being developed under the management of E. W. McClave of Easy City. The old shaft is 80 feet deep and the new shaft being sunk is down 100 feet and crosscutting is being done. Half a ton of ore a day is being taken out in development work.

The Pittsburg-Jerome M. Co. has sunk 160 feet on their proposed 1000-foot shaft on the Pittsburg, 2 miles south of Jerome. They will build a 1½ mile wagon road from their camp to the county road, as now everything has to be packed in over trails. C. H. Pratt is president, T. H. Houlette vice-president and S. B. Whiery secretary-treasurer, all of Pittsburg, Pa. D. S. Cochran is the engineer at Jerome, and W. A. Edeburn is consulting engineer.

### CALIFORNIA.

#### Amador County.

(Special Correspondence).—The chlorination plant at the Kennedy mine, near Jackson, has been remodeled and the new roasting furnace has been in successful operation since November. Crude oil is used as fuel and band rabling is employed. A small portable boiler is used to make steam for the oil burner. The old furnace is still standing, but is not being used. Sinking has ceased temporarily in the vertical shaft and the station and chute for the 2700-foot level are being cut. After the crosscut for this level has been started sinking will be resumed and another level opened at 2850. The 100 stamps are kept in constant operation.

Jackson, Jan. 31.

(Special Correspondence).—The Sutter Creek G. M. Co., J. Schenck manager, is developing the Treadwell mine on Sutter creek, 6 miles west of Sutter Creek, near Volcano. B. K. Worley of Seattle, Wash., has been made superintendent.

Volcano, Feb. 1.

At the Wildman mine in Sutter Creek twenty stamps are handling the ore from the 1400-foot level. The new mill at the South Eureka mine at Sutter Creek is crushing 100 tons per day, mostly ore from the 2400-foot level. The new and old mill are saving three tons of sulphurets daily. Sinking has been discontinued at the Zeila mine near Jackson while a station is being cut at the 1500-foot level. They are drifting toward the ledge on the 1400-foot level. The cement foundations for the new hoist have been completed. At the Kennedy mine they are putting in the lathes and other machinery to do all the repair work on the ground, except castings. Some repair work is being done to the first sixty stamps of the mill. With the constant jar of the stamps it has been found that the mortar posts have become worn on their cement bases. To remedy this it is proposed to drill into the solid cement and introduce wood blocks under the posts. One battery will be treated in this manner at a time, so that not more than ten stamps will be hung up at any one time.

Marsino & Sons' gravel mine, north of Volcano, is being surveyed and a shaft will be sunk and a 700-foot tunnel driven.—The machinery of the Stockton M. Co. at Mokelumne Hill has been bought and is being moved to the Burlington mine, near Sutter Creek, by Superintendent L. Smith.—A survey is being run from Martells to Sutter Creek and Amador City by the Ione & Eastern Railway so as to pass the principal mines.

#### Butte County.

The Yuba river, near the first barrier of the restraining dam being built by the Government on the upper Yuba, is to be worked by dredgers digging to depth of 60 feet, by W. P. Hammon of Oroville. On the Feather river, 35 or 40 feet has been the limit.—It is reported that a new dredger will be built on the Baggett lands, south of Oroville. These lands are 1 mile or more from the nearest point to the river and are high lands quite removed from the present dredger district.

#### Calaveras County.

On the Licking Fork, near West Point, Haley Bros. have sold a claim to an Oakland company, who are building a 3-stamp mill.—The Swiss mine in Railroad district is being worked.—In the Lincoln district, Congdon & Lunt are working the Galena claim.—The Outlook mine at Mokelumne Hill, W. T. Robinson superintendent, has closed down temporarily, a cyanide plant to treat the sulphurets being needed. A. Noyes has gone East to make arrangements for putting in a plant and ten stamps will be added to the mill.—On the Boston mine the water is being kept out, pending a sale.—The Ponge mine at Railroad Flat is running and more men have been put on. The mill is running with five stamps and five more are to be added soon.

Work has started on the Johnson mine, near Angels, under the superintendency of J. B. Luddy. A shaft is to be sunk through the gravel 300 feet, when crosscuts will be run 500 feet or more to tap the quartz ledges on both sides.

#### El Dorado County.

A. F. Levitt is grading for a 10-stamp mill to be built on the Red Raven mine, near Shingle Springs, which they expect to have in operation by the middle of April.—The Gopher-Boulder mine, near Kelsey, is to be started by John Sipp.—It is reported that the California-Bangor slate quarry, near Kelsey, will start up.—The American River Con. M. Co. of Placerville, organized to mine on the American river below where the water is diverted by the electric company, are preparing to commence operations the coming summer.

#### Kern County.

The Sunshine mine, 2 miles southeast of Randsburg,

is working twenty men on its mine and mill. T. W. Atkinson is superintendent.—An electric motor will be put in to haul the ore from mine to mill at the Yellow Aster at Randsburg, replacing mules.—The Searles M. & W. Co. are working the Summit diggings, north of Johannesburg, piping water 6 miles from the El Paso hills. Gasoline engines are used for power. A. Anderson of San Francisco, the principal owner, has been visiting the mine. C. Teagle is superintendent.

#### Placer County.

W. H. Wales, N. J. Pearson and N. T. Collins of Colfax have struck pay gravel in the Big Boulder drift mine in Secret canyon, 4 miles from Colfax.

#### Plumas County.

At Taylorsville A. Dragovich has men at work on the Austrian Syndicate mines.—T. McRele is manager at the Blue Bell mine at Taylorsville.

Superintendent J. D. Whitney has started machine drills in the New York mine, near Greenville. The mine was temporarily idle for several months while machinery, including a drilling plant, was being put in.

#### Sierra County.

It is reported that rich ore has been developed in the Empire mine at Gold valley. The company has fifteen men at work.

#### Tuolumne County.

R. Marshal has bought the Hidden Treasure quartz mine, near Tuolumne, from T. J. Ryan.—G. Weisbaum is putting machinery on the Brindle Pup mine belonging to R. Morgan.—T. F. Corcoran has sold to T. F. McGovern the Big Chunk mine, 1½ miles northeast of Jacksonville.—The Longfellow Co. at Big Oak Flat has bought the Big Betsy property and is moving the surface equipment to the Longfellow. W. S. Elkins of Colorado has sold to the Elkins M. Co. the Rainbow quartz mine, near Texas Bar, on the Stanislaus river, the Iron Cross, Mountain Key quartz mine and mill site and the Mayflower quartz mine, near Pine Log.—Near Jupiter a prospect shaft is being sunk on the Stockton gravel mine. A 12 H. P. gasoline engine has been put up.—The Mountain Belle, near Soulsbyville, has started work.

Near Groveland it is reported a 5-foot vein of big-grade ore has been found on the Justice mine, one of the Big Creek group.—The sixty stamps of the App mill are crushing ore from the mine at Quartz. Eighty men are at work.—The Santa Ysabel at Stent is being worked by thirty men.—The 20-stamp mill of the Dutch mine at Quartz is running continuously.—Ore is being packed from the New Albany mine, on the north fork of the Tuolumne river, to the Grizzly mill, near Carters.—G. F. Bartlett is developing the Mayflower mine, near Carters.—S. Knapp has bought and will develop the Wiedekind mine at Pine Log.—New machinery is to be bought for the Black Hawk mine, near Soulsbyville, which is closed because of the insufficiency of present equipment.—A. C. Johnson is running a 150-foot crosscut tunnel on the Mohican, 1 mile east of Tuolumne.—Curley, O'Brien & Fleming have struck good ore on the Bonanza, on the Tuolumne river, 4 miles above the Mohican.

### COLORADO.

(Special Correspondence).—A 40,000 H. P. electric plant to supply Leadville and other camps in the vicinity is to be built on the Grand river near Glenwood Springs. The power will be furnished for mining and domestic purposes. This is the second largest plant of its kind to be projected in the State. The other one is on the Animas river, between Silverton and Durango, in the southern part of the State. The power plant near Telluride is supplying power to different mines at Telluride and Ouray, and is said to be a commercial success. The power is transmitted a number of miles in several instances.—The Newhouse tunnel, which is now 14,750 feet in length, is reported to have tapped the Saratoga vein in Russell Gulch. This tunnel was started in 1891, but has been closed down on several occasions for various reasons. When completed the enterprise will be used for the transportation of ore as well as drainage.—An eight-hour bill has passed the Assembly, now in session. There is some speculation as to whether it will be passed by the Senate as it now reads. It is understood the utility corporations in the State are opposing its passage. The bill includes all men employed around mines, mills, smelters and in various other enterprises.

Denver, Jan. 30.

In 1903, according to Government report, Colorado produced minerals to the value of \$46,506,000; gold value was \$22,540,100; silver, fine ounces, were 12,990,200; copper, 4,158,368 pounds; lead, 45,554 tons; iron ores, \$787,824; manganese ores, \$55,710; bituminous coal, \$7,381,463; coal tar, \$30,506; quarry products, \$708,043; brick, tiles and pottery, \$2,068,310; Portland cement, \$436,535; clay, \$41,454; petroleum, \$431,723; natural gas, \$14,140; mineral waters, \$127,078; spelter, 877 tons; zinc oxide, 119,124,160 pounds; lead-zinc pigments, 4,950,000 pounds; spiegeleisen, 6882 long tons.

#### Chaffee County.

The Stratton-Massachusetts Gold Mines Co. at Buena Vista is sinking its shaft to the 200-foot level with a new steam drill. The management intends to drift under the large quartzite dyke and begin the stoping of ore at once. A 125 H. P. engine and boiler and blacksmith shop have been put in.

#### Clear Creek County.

The Orinoco M. & T. Co., near Idaho Springs, will put machinery on the Orinoco tunnel by the middle of March and will complete the tunnel which is in nearly 500 feet. S. W. Miller is manager.

#### Custer County.

Custer county, in 1904, is estimated to have produced: Silver, \$129,000; gold, \$101,000; copper, \$10,000; lead \$21,000. The lead producers were all idle for the year, but the lead mined was taken from properties where other and more precious metals predominated. At Silver Cliff the new experimental plant for the treatment of low-grade ores is completed and work will soon begin.

## Gilespie County.

W. S. Bell of Chicago has a lease and bond on Huddleston Nos. 1 and 2, on Winnehago hill, near Central City. The main shaft, 250 feet deep, is to be sunk 100 feet more. The lower tunnel is to be continued. A Merri- 10-ric is superintendent. —The Gold Dirt M. & M. Co. is building a 10-stamp mill in Campbell gulch, near Central City. It is reported that the treatment will be first by amalgamation, then by cyanide and finally concentration. The stamps will weigh 1100 pounds and have a rapid drop, fifty tons being the intended capacity of the ten stamps.

The Scissler mine on Missouri flats, in Russell Gulch, has been started. —The Newhouse tunnel is opposite the Missouri mine at the present time, and C. Pishon, manager of the Missouri, says that the water is leaving his mine and being drained into the tunnel. This will help the management in working the mine, as the shaft will be dry. Pishon has started up the Fraction mine. —The Lutz mine in Russell Gulch has been started to furnish water for the boilers in the Old Town and Peawabie mines.

## Gunnison County.

The Monometallist M. Co. has been formed with D. P. McNeill of Tin Cup, J. Cullen of St. Paul, Minn., H. A. Fulton, J. W. Singleton, J. C. Gilbertson of Eau Claire, Wis., J. Brennen of Ironwood, Mich., and G. Stenz of Ashland, Wis., as directors, to operate in Taylor park. —A. Berg has cut a number of veins in driving a 500-foot tunnel on the Phillips group in Jones gulch, near Pitkin.

## Jefferson County.

An additional smelter has been blown in at Golden by the Independent S. & R. Co., which, together with mechanical improvements, will increase the capacity of the smelter to 300 tons of ore per day. The company will add crushers and rolls to their sampler at Black Hawk.

## La Plata County.

(Special Correspondence).—A snowslide at the Empire mine, at the head of La Plata river, carried away the cook house, killing one man and injuring several others. —The May Day has had a Crano ore washer in operation for some time with good results, and has been making steady shipments. This company is using both air and electricity. Drifting and stoping are going on from the 500-foot adit, and practically all the vein matter is being shipped, the width being 1 to 7 feet. An adit is being started to cut the vein at a depth of 850 feet. A wire ropeway is being built to deliver the ore from the present workings to the county road, saving 2 miles over a steep road and trail, and it seems likely that the R. G. S. will build at least as far as the tramway terminal this coming season. —The Bonnie Girl M. Co. is working on the grade for the remainder of the mill building, and it will soon be ready for the frame and the leaching tanks. —The Chief M. Co. has doubled its force and is driving the 700-foot adit as rapidly as possible since the new strike near its property. —The Durango Girl has increased its force and will soon ship.

Mancos, Jan. 30.

## Ouray County.

(Special Correspondence).—The Atlas M. & M. Co. are installing electrical machinery for power purposes, to be used in driving the 2000-foot crosscut. Preparations are also being made to put in a cyanide mill on the property as soon as the weather will permit. The company owns 205 acres in Sidney basin. They have 1200 feet of development work done on the vein. The ore is free milling. Manager F. Carroll states that 70% of the values can be caught on the plates. The mill will be put on Soffles creek, 2500 feet from the mouth of the crosscut.

Sneffles, Jan 31.

## San Juan County.

The Hamlet M. & M. Co., near Howardsville, 7 miles north of Silverton, in Maggie gulch, will build a 50-ton mill.

The Silver Lake tramway line near Silverton, which was so badly damaged by fire on December 15, will be rebuilt by March 1. The mill of the Silver Lake mine remains idle, but at the mine 100 men are employed. —The Bagley crosscut, 1 mile above Animas Forks, is 400 feet long and is making headway as rapidly as possible with two shifts of men with machine drills. Electric power is being used. —The Mayflower group in Arrastra basin is being worked by J. C. O'Neill and associates of Chicago, Ill. A contract has been let for the continuation of the crosscut which is now in 350 feet to intersect the Mayflower vein.

C. C. Harding of Silverton is putting an electric light and power plant on the Old Hundred; the new aerial tramway is completed.

The Edward-Ruth G. M. Co. has been formed to work the Esmeralda properties in Minnie gulch, near Silverton, and will build a mill for concentrating and cyaniding. The directors of the company are W. J. Ratlie, R. W. Hollis, C. A. Klotz, L. Rosenfield and D. E. Carmichael, with the principal office in Silverton.

## Summit County.

P. Fisher is working on the Queen of the West mine, near Kokomo, driving to cut the ore shoot. —The Michigan mine, on Sheep mountain, near Kokomo, is shipping fifty tons daily. —The Union Con. group, which has been using an electric drill in their tunnel, will put in a compressor and air drills. Until recently they were running the electric drill with water power, but now the water is mostly frozen. —The Result and Lawrence, on Gold hill, are driving long tunnels. —The Robert Emmet group, sold to Cleveland parties last year, will be worked. —The contractors on the Bird's Nest, near Kokomo, are pushing development on the crosscut tunnel.

## Teller County.

The annual report of the Vindicator Con. M. Co., at Cripple Creek, for 1904 shows: Net production, tons, 15,344.329; gross proceeds, interest, rent, water and ore, \$490,279.51; total expense, \$315,494.34; profits from mining, \$174,785.17. The labor cost was \$120,007.85.

## IDAHO.

## Idaho County.

The Standard mine at Roosevelt, O. M. Snyder superintendent and J. Cawley foreman, is between the Sunny-side and H. Y. It is reported that a vein 50 feet wide has been cut, running from \$20 to \$500 per ton.

The main shaft of the Oregon in the Four-Mile district, near Grangeville, is 100 feet deep. A mill is to be put on the property in the spring.

## Shoshone County.

Work has been resumed by the Iron Spar M. Co. on its property south of the Leslie near Wallace.

The Federal M. & S. Co., the Morning mine and the Hecla M. Co. will institute provident and accident insurance associations for their employees, commencing Feb. 1. Recognizing that mining is a hazardous business and occupation, and notwithstanding the adoption of the most stringent rules and regulations by the mining companies to protect their employees from injuries while in the performance of their duties, the associations are formed for the benefit and protection of both employee and employer, and to provide a fund to render assistance to the injured during the period they are incapacitated for work or to their families in case of death. The system that will go into effect here is patterned after the one in vogue at the Drumlunnon mine in Montana. There will be three distinct associations, one for each of the three concerns. They will be similarly but entirely separately operated. That of the Federal Co. will be known as the Federal Provident & Accident Insurance Association. The other two will be the Morning Provident & Accident Insurance Association, and the Hecla Provident & Accident Insurance Association. The Federal Association will be governed by a board of six trustees, three of whom will be elected by the employees and three by the company. Of the three elected by employees one each will be chosen from the Burke, Mace and Wardner mines of the company. Each of the other associations will be governed by four trustees, two of whom will be elected by the employees and the other two by the company. It will be imperative for every employee of the companies to become a member of the association and subscribe \$1 to the relief fund for each month, or any fraction of a month over ten days. For a fraction of a month less than ten days the dues or subscription will be 10 cents a day. The amount of the subscription is to be deducted from the wages at each pay day or at the time the member's services in the company cease, and paid to the association. For every \$1 monthly subscribed by the employees the mining companies will contribute monthly 50 cents. In consideration of this payment the association guarantees to protect the mining company from all liabilities on account of injuries received by a member of the association during his employment by the company. The employees are given insurance at a low rate. Every employee of the companies also pays \$1 a month hospital dues. Hereafter if an employee sustains an injury in the performance of his duty, not only medical attendance and care are assured, but in addition a weekly stipend that will serve to provide the wants of his family during his incapacity. In case a member of the association is disabled by reason of an accident, the articles of the association provide that he shall be entitled to receive relief from the funds of the association at the rate of \$10 per week for every week he is unable to work, not to exceed ten weeks. In the event of the death of a member of the association from injuries received while in the employment of and at work for the mining company, a surviving wife and children shall be entitled to receive \$1500 out of the funds of the association. When so paid, "all obligations on the part of the association and the mining company on the account of such injuries or death shall cease," and in no case shall such money be applicable to the debts of the deceased or liable to be attached by his creditors, the obligations of the association not being to the deceased himself in such event, but to the widow and children. There is no liability in this case unless the death occurs at the time of or within six months after the injury, and that the latter is the approximate cause thereof. In the event of a member becoming totally blind, or so crippled or lamed as to be wholly and permanently disabled from all labor whatsoever thereafter through accidental injuries received while actually engaged in work or labor for the mining company, such member shall receive out of the funds of the association \$1500 in full for all claims and demands; and when a member shall in like manner lose the sight of one eye, or become wholly crippled in one limb, and thus become partially unfit for labor for all time, he shall receive out of the funds of the association \$750 in full payment for all claims, and these amounts will be in lieu of all weekly compensation, and when paid "all obligations on the part of the association and the mining company on account of such member shall cease." The articles provide that neither a member nor his widow or children shall be entitled to any relief when the injury or death is the result, in whole or in part, of drunkenness, fighting, immorality or the criminal negligence of such member; but the board of trustees shall have the power, notwithstanding such fact, to grant such relief as it may deem in its discretion just and equitable. About 1500 men will become members of the three associations, who will pay into the treasuries \$1500 a month. The mines will contribute \$750 a month, making a total subscription of \$2250 per month into the relief funds of the three associations.

## MONTANA.

## Beaverhead County.

The Silver Fissure M. Co. has been formed to work the Polaris mine and adjoining claims in the Lost Cloud mining district, 40 miles west of Dillon. The directors are H. Willets of White Plains, N. Y.; E. Cochrane of New York City; H. H. Arnstead of Butte, Mont.

## Broadwater County.

The 100-ton concentrator, built by Caird & Hawkesworth of Helena for the Mason properties near Hassel, will be running by February 10. They are running a 1200-foot tunnel to tap the ore bodies at greater depth, being in over 700 feet.

## Fergus County.

J. A. Drake of New York has paid \$25,000 to take up an option on an interest in the North Moccasin mine, near Kendall. Four thousand feet of ground has been prospected by diamond drilling.

At the Kendall mine, North Moccasin, Finch & Campbell of Spokane, Wash., have made a raise from the 500 level to reach the surface. When timbered the hoist will be set to use it as a compartment shaft. It is expected that the hoist will be in operation to the 500 level in about four months, and the shaft will then be driven on to the 800 level to encounter the new ore body located by the diamond drill. The shaft will be continued to the 1000-foot level. A 150 H. P. electric hoist, having a speed of 1000 feet per minute, large sinking and station pumps and a new compressor have been ordered. The Kendall is employing 100 miners and turning out 300 tons of ore daily.

## Silver Bow County.

The Speculator M. Co. at Butte has raised its output from 150 tons per day to 350 tons and expects to continue until it produces 500 tons daily. Recent development work in ground acquired by the company is responsible for the increase. It is claimed that the Edith May, bought by the Speculator, contains a vein of copper-silver ore, and the company is now drifting in it. The Speculator mine is developed by a 1600-foot three-compartment main shaft sunk in the granite and connected with the ore bodies by crosscuts and winzes. —At the Alice mine at Butte, Manager Buzzo has opened the zinciferous vein at the 400, 500 and 600-foot levels and repaired the stations and crosscuts leading from the stations to the vein. The Montana Zinc Co., which has overhauled the 60-stamp mill of the Alice to treat the zinciferous ore, is ready to commence its final test run on 500 tons of the ore. This ore is now in the bins. It averages from 12% to 20% zinc, from 6% to 8% lead, from 6 to 10 ounces in silver and from 60 cents to \$1.60 in gold per ton. The vein from which it was taken is 20 feet wide on the 600-foot level, from 20 to 30 on the 500 level and from 25 to 50 on the 400 level. Above the 300-foot level it merges into the oxidized body. A mine carload of it weighs 1900 pounds, which is 700 pounds more than a carload of the oxidized ore weighs and 500 more than a carload of the gray class or sulphure ore. In the Parrot addition, fifteen claims are yielding copper-silver ore in paying quantities. They are being worked principally by individuals. The Butte & Boston and Geyman companies are developing two claims there and extracting ore.

## NEVADA.

## Esmeralda County.

(Special Correspondence).—The Royal M. Co. of New York is a new company organized to prospect mining claims they own, just north of the Sandstorm and Kendall mines, with a drilling outfit. These claims consist of the Sol, Kemp, Frear, Cox, Brooks and Hen, and adjoin the property of the Sierra Nevada Development Co., near Columbia.

The Goldfield-Tonopah Con. Mines Co. of Chicago, who are operating on the Red Butte No. 1 at Diamondfield, in their crosscut on the 70-foot level have struck a vein carrying good values and with defined foot and hanging walls. This extends the Diamondfield belt northerly beyond the Quartzsite and Great Bend mines. Red Butte No. 1 is northwest a short distance from the Great Bend and east of the Tonopah Club. This strike on the Red Butte No. 1 is the latest development at Diamondfield. J. D. Hoff is consulting engineer for these mines.

Diamondfield, Jan. 27.

## Lincoln County.

It is reported that active operations are to be started by the Deer Lodge M. Co. at Fay, based upon examination by J. J. Trenam and F. W. Galigher. —At the Quartette mine at Searchlight Assistant Manager G. B. Wilson and Millman P. J. Johnson have put in electric bell signals, using a lever instead of a push button, causing less chance for mistakes. The amount of water in the shaft is increasing. —The 100-foot upraise from the face of the Empire tunnel to the surface has been completed. —De Berry & Kaiser are placing a whim on the Mondamin mine, near Searchlight, preparatory to sinking and drifting to the hanging wall. The shaft is down 125 feet. —The mine operators at Searchlight and vicinity have agreed upon a wage scale and card system, to become effective on Feb. 15, 1905. All employees working underground must be raised or lowered, one way, on their own time. Eight hours shall constitute a shift's work underground; on top it shall be nine hours. Miners employed in sinking winzes shall receive \$3, except when in wet ground, when the wage shall be \$3.50. Mining in dry ground \$3, mining in wet ground \$3.50, up-raising or in bad air \$3.50, sinking in dry ground \$3.50, muckers in wet ground \$4, muckers in dry ground \$3, trammers in wet ground \$3.50, engineers \$3.50, timber framers \$3.50, timbermen \$3.50, tool sharpeners \$3.50, skip tenders \$3.50, special pumpmen \$4, blacksmiths \$4. The agreement has been signed by the Quartette M. Co., Searchlight M. & M. Co., New Era M. Co., Pompeii M. Co., Santa Fe M. Co., De Berry & Kaiser, Southern Nevada M. & M. Co., Duplex M. & M. Co., Good Hope mine, Saturn M. Co., Wilson M. Co., Mondamin mine.

## Nye County.

It is reported at Liberty, 20 miles north of Tonopah, that the Cramps of Philadelphia are to put up two large mills as soon as the railroad can transport the machinery, which has been ordered and shipped.

The Eureka Sentinel says the best route to Goldreed, in the Kawich range, is from Eureka to Fish Creek, 16 miles; Fish Creek to Willow Creek, 22 miles; Willow Creek to Hicks', 18 miles; Hicks' to Moore's, 14 miles; Moore's to Hot Creek, 18 miles; Hot Creek to Twin Springs, 20 miles; Twin Springs to Revell, 19 miles; Revell to Goldreed, 22 miles.

## NEW MEXICO.

## Colfax County.

The steam dredger on the Moreno property, near

Elizabethtown, which is being operated by the Oro Dredging Co., is being repaired for work this spring.

#### Grant County.

The one furnace, which was blown in at the Comanche smelter at Silver City, January 1st, has been in continuous operation ever since. The company is contracting for ore from various parts of New Mexico and Arizona.

#### Luana County.

E. E. Burdick has recently purchased the Hancock, near Hermanos district, and will start development. The Big Helena and Hard Times mines, near Cook, have been bought by the Tri-State M. Co. J. E. Britton is superintending work.

#### Otero County.

The Standard Lithograph Stone Co. is putting in machinery near Higbolls.

#### Santa Fe County.

The Sunny Slope M. Co. has resumed work at San Lazarus, in the New Placers district.

### OREGON.

#### Baker County.

T. M. Anderson will put a steam hoist on the Uncle Sam mine on First creek, east of Malheur. The double-compartment shaft is down 85 feet and is to be sunk till 300 feet deep. The placers of the company are to be worked this spring. The Daisy M. Co., adjoining the Uncle Sam, expect the 30-stamp mill that they are building to be completed by Feb. 15.

The 10-stamp mill for the Belcher mine, near Greenhorn, is to be put up when weather permits. F. L. Daines is superintendent. H. H. Nicholson is in Denver completing tests on the cobalt ore from the Standard mine preparatory to ordering a reduction plant.

#### Lane County.

W. B. Hartley, in charge of the Star Consolidated property at Bohemia, reports that 3000 feet have been driven and that a new ledge has been opened. A mill may be put up during the present year.

#### Josephine County.

C. D. Smith is working the White & Benson placer mine on Humburg creek, 2 miles above Applegate. The Sucker Creek M. Co. are prospecting on Sucker creek, 10 miles above Illinois river, near Grants Pass. The method is to sink shafts to the bedrock, the creek bottom being cross-sectioned at regular intervals. Should the prospecting prove satisfactory the company will put in a dredging plant, but will use a steam shovel rather than a bucket dredger. P. Rowe is president, W. H. Townsend vice-president and H. Warner secretary and treasurer, all of Seattle, Wash.; W. Symmes of San Francisco, Cal., is the manager. The work at the mine is under the supervision of H. Warner and W. H. Townsend. On the Coast Range divide, 16 miles west of Kerby, H. J. Isaacs of Grants Pass and H. Mills, D. Mortiny and G. Howard of Placer, have found a promising copper-gold vein.

A rich strike of free milling ore has been made on the 300-foot level of the Granite Hill mine. The ledge at this point has a width of from 5 to 7 feet. The vein dips about 65°, and is close and compact with well defined walls. W. J. Morphy is manager, L. Y. Wickersham, superintendent. The new turbine, developing 100 H. P., is installed. The power from the turbine is transmitted by dynamo and motor. The big pump has been moved from the 237-foot level to the 300, and a smaller pump is set in the old station. The three pumps installed obviate all danger of flooding, as they have a combined capacity of 22,000 gallons an hour. The present battery of ten stamps will be doubled.

### SOUTH DAKOTA.

#### Custer County.

W. W. Olds, president of the Ruberta M. & M. Co., has purchased machinery for a cyanide annex that is to be operated with the stamp mill at the Ruberta mine, west of Custer. The Saginaw M. Co. has blocked out 200,000 tons of ore in its mine 8 miles northwest of Custer. A crosscut is being run from the lowest workings on the property to open up more of the ore above. A number of diamond drill holes put down on the dip of the vein have found three ore ledges of large size, which will average better than \$8 a ton at a depth of 500 feet. The company has had a number of carload tests made on the ore and a mill will be built this season of 100 tons capacity.

The officers of the Interstate M. & M. Co., operating near Custer, are: J. H. Godden, Emmetsburg, Iowa, president; J. Donegan, vice-president; E. H. Soper, Emmetsburg, Iowa, treasurer; A. G. Hortue, secretary; W. R. Millham, Custer, general manager.

#### Lawrence County.

(Special Correspondence).—Several years ago when the old shaft of the Horseshoe Company was sunk just above Terry some ore was found near the bottom of the shaft, but as the first assays did not indicate an ore body of payable value, little attention was given it. During the progress of work recently done there further tests were made and it is now known that there is available a large quantity of a paying grade of ore. The shaft had passed completely through the ore body, but the new work is demonstrating that appearances are sometimes deceiving, for it is said the ore is of better grade than that which has been treated in the Horseshoe mill for some months past. The shaft had been idle for years and filled with water. It was thought that if the water was raised from this shaft it might have a beneficial effect on the amount of water in adjacent workings, where it could not be handled as cheaply as through the old shaft. When the water was removed from the shaft prospecting revealed the ore body now being developed.

Terry, Jan. 27.

It has been unofficially announced that the March dividend of the Homestake Company will be 50 cents per share instead of 25 cents, the usual amount. The

Safe Investment Co., developing claims on Box Elder creek, near Perry, contemplates building a mill. A contract to sink a shaft 100 feet deep and drive a crosscut has been let. It is reported that a large body of gold ore has been exposed on the adit level. J. A. Webb of Deadwood is superintendent. The Victoria M. Co. is preparing to build a mill on its mines near Spearfish canyon and Squaw creek. The ore occurs in limestone, and development work has blocked out a large tonnage of ore. G. S. Jackson of Deadwood is manager.

The statements of milling operations of the Spearfish G. M. & R. Co. for 1904 show:

	Net Tons.	Heads.	Tails.	Recovery Average	Total Cost	Per Ton.
January	4,111.2	\$4,652	\$ .866	15,709.31	\$13,285.90	\$3.22
February	4,544.1	4,631	.71	21,534.34	12,355.50	2.55
March	4,723.8	4,627	.832	17,187.44	12,555.22	2.59
April	5,539.69	3,647	.828	17,310.24	12,650.22	2.28
May	5,587	3,471	.457	18,500.46	11,557.99	1.97
June	5,361	3.33	.452	16,184.80	11,604.78	1.98
July	5,723	3,074	.437	16,102.02	11,503.23	2.01
August	5,349.6	3,055	.51	15,307.36	12,107.50	1.45
September	7,276.6	2,611	.674	15,991.57	11,508.84	1.59
October	7,171	2,734	.628	14,855.74	11,473.60	1.60
November	7,125.8	3,007	.55	15,499.59	12,455.05	1.74
December	6,279.48	3,065	.576	12,998.03	12,531.28	1.994
	72,871.37			197,490.89	\$145,361.30	
Average Tons	Per Ton	Per Ton	Per Month	Cost Per	Per Ton	
6,062.61	\$3.499	\$ .635	16,457.57	\$12,135.94	\$1.998	
Average recovery per ton						2.71
Average cost per ton						1.998
Average profit per ton						.712

The Jupiter mine, near Deadwood, is being developed by W. L. McLaughlin and E. Manion. The Mining Review says that the Branch Mint M. & M. Co.'s plans embrace the construction of the largest wet crushing cyanide mill at Galena, the plant to contain 180 stamps and have a daily capacity of 900 tons, maximum; a hoisting plant capable of raising 1000 tons of ore per day from a depth of 1000 feet; this hoisting works to be under the same roof as a crushing plant, equipped with the Gates crushers, and the operation of a railway for ore and supply haulage between mine and mill. In the mill twenty stamps are completed. At the hoisting works the grading is finished, and a portion of the machinery set in position. Large Scotch marine hoilers are being put up. The railway grade is completed, except a few cuts in solid rock. J. D. Hardin is manager. P. T. Newitt, general manager of the Lexington Hill Co. at Deadwood, has encountered the quartzite in the 1400-foot tunnel, 500 feet below the surface. With this tunnel as a starting point, raises will be made to the surface, with the stopes in the various ore bodies. Ore will thus be broken to the best advantage, dropped to chutes at the tunnel and trammed to the mill, which is a few yards from the portal of the tunnel. The company intends to increase the capacity of its mill by adding forty stamps, with cyanide annex.

#### Pennington County.

The Wealthy group of mines near Keystone has been sold to the Eagle Rock M. Co. There is a 20-stamp mill on the property, which is to be put in repair immediately. A cyanide plant is to be built by the Mainstay M. Co. at the Bismark mine, near Keystone. T. R. Griffith is general manager. The 10-stamp mill of the Tykoon mine, northwest of Keystone, has started after a short shutdown for repairs.

The Mainstay M. & M. Co. of Keystone will equip its 30 stamp mill with a complete cyanide plant. T. R. Griffith is manager. The Black Hills Electric Power & Mining Co., working on Rapid creek, intends to install a large plant capable of handling 1000 yards a day on its placer mine.

### UTAH.

#### Salt Lake County.

At the Yampa smelter at Bingham the new reverberatory stack and building which is to surround it is finished. The second roasting furnace, installed by Superintendent H. C. Bellinger, is said to be doing its work very satisfactorily and is producing a much better grade of matte than was possible with the original furnace. The Yampa is producing fifty tons of matte a day.

A rich lead vein has been struck in the Tilden No. 2 tunnel of the old Phoenix property. The company intends widening the tunnel so that electric motor cars can be used in transporting the ore from the stopes to the ore bins, a distance of 2800 feet, and is also considering means for more rapid and economical shipment to the smelters—probably by a gravity wire tram across the gulch to the Copper Belt. The ore bins are being enlarged from a capacity of 200 to 500 tons. H. A. Gebhart, Jr., is superintendent. The Yampa at Bingham has put an electric generator and motor into the mine to dispense with horses in the tunnel. The work is under the supervision of Superintendent W. J. Craig.

### WASHINGTON.

#### Ferry County.

The Quilp mine on the Republic & Kettle River Railway, near Republic, will resume work and start shipping. E. L. Tate is manager.

Superintendent Case of the California mine at Republic reports that the shaft has been unwatered sufficiently to admit of operations as low as the third level, where there is stopeing ground left, and he will put men to work removing the ore as soon as some needed timbering is attended to. He thinks there is ore enough left in the old workings to keep the miners busy stopeing for several months. The Gold King M. & M. Co., whose property adjoins the Belcher mine on the north at Republic, is considering resuming work. G. S. Moody is president, T. M. Hammond vice-president and R. W. Hunner secretary and treasurer. Work has been resumed on the Elk mine at Bodie camp with a small force.

#### Okanogan County.

The Buckeye Free G. M. Co. at Chesaw is working three claims, with a tunnel which follows the ledge. The ore is being stored in bins near the mine, awaiting the completion of a 10-stamp mill. At the Bimetallie, south of Chesaw, W. C. Peay, the general manager, says that the company will put up a matte furnace this summer for the reduction of Bimetallie ores. Men are

working the Grant mine on Copper mountain, near Chesaw, under the management of J. A. Anderson. The Opal and the Ben Harrison companies have joined in putting up a 10-stamp mill at Cbesaw, and have the machinery on the ground. The completion of this will give the camp four mills.

The Ruby M. Co. on Chopaca mountain, near Night-hawk, which has been doing prospecting and development work on its claims for eighteen months, has uncovered good ore. A shaft was sunk 200 feet on Chopaca mountain and two crosscut tunnels were run. Exploration of the main ore body shows that the vein is from 3 to 20 feet in thickness. It has been uncovered 200 feet deep and 1400 feet in length. The main body of ore is a soft sulphide, easily worked and lying in an outside casing of talc, surrounded by granite. The values are silver, gold, copper and traces of zinc and lead. The shipping ore averages \$50 a ton. Five hundred tons have been already taken out and six 200-foot chutes in the mine have been filled. J. M. Hagerty, the president of the company, has been East with a quantity of samples of the ore, in order to have expert chemical analysis made and a reduction process devised that is adapted to the peculiar chemical conditions. Baker & Burwell of Cleveland, Ohio, have devised an electric chlorination process. The firm has contracted to install a 20-ton plant for the reduction of this mineral, at a guaranteed cost of \$2.50 per ton. The electrical current is to be supplied by the Similkameen Falls P. & Dev. Co.

#### Stevens County.

The Turk M. Co., working the Turk mine at Deer Trail, has shut down the new smelter which was recently installed. A bell and hopper feed is being put in on the preliminary furnace. This is a water jacketed Blanchard furnace, 3x5 feet inside. The company is building a wagon road from the Spokane river at the Detillion bridge to the mine, upon which a large 110 H. P. traction road engine may be used in hauling coal, coke, etc., to the mines. The materials will be hauled by teams, as they now are, to the Detillion bridge and taken from there to the mine by engine.

#### Whatcom County.

In a report urging that a wagon road be built over the present trail east of Marble mountain, F. C. Teck shows that in the Slate Creek district 56 miles of trails and 83 miles of wagon roads have been built at a total cost of \$185,000. There are 101 buildings in the district, which cost \$62,000. The mines and prospects of the district are developed by 4435 feet of prospect tunnels and 11,377 feet of working tunnels, shafts, etc., at a cost of \$157,694. The mines have 9330 tons of ore on the dump and 432,000 tons blocked out, ready to mine. The average value of the ore is \$13 per ton and the total value of ore on the dump and blocked out is \$5,737,290. There are thirty-five stamps in the district. The output prior to 1904 was \$385,000 and the output including 1904 has been \$417,000. There are 888 tons of concentrates at the mines, valued at \$79,200. In 1904 208 men were employed in the district. The distance from Rockport, the present terminus of the Great Northern Railway, to Slate creek or Barron is 64 miles. The distance to be covered by the proposed wagon road from Marble mountain to Mill creek is 46 miles. The distance to the railroad via the Methow and Columbia river route to Wenatchee is 150 miles. Freight charges by the present route from Wenatchee are: From Wenatchee to Brewster, 70 miles by steamer, 50 cents per 100 pounds; from Brewster to Robinson, 68 miles by freight wagon, \$1.10 per 100 pounds; from Robinson to Barron, 12 miles by narrow wagon, 50 cents per 100 pounds. This makes a total of \$2.10 per 100 pounds for the 150-mile trip.

### FOREIGN.

#### AUSTRALIA.

##### Queensland.

The U. S. Consul at New South Wales reports that during the past year a mine of graphite has been successfully worked on Mount Bopple, 3 miles from Netherby, on the north coast line, and 35 miles from Maryborough. The material found is of very good quality, and the output is likely to be considerable. At a depth of 32 feet 35 tons of graphite were obtained in cutting through a large mass, and on continued sinking operations, fine seams varying from 1 foot to 6 feet have been reached. Several shipments have been made to the paint manufacturing firms in the south, and have brought about \$50 a ton. Trial specimens have also been sent to some large firms in England and Germany. The famous mines in Cumberland, England, worked as far back as 1550, have given out, and the main supply of British and American graphite manufacturers now comes from Ceylon. The crude ore, in which there is a mixture of silica and sulphur, is sent to the manufacturers for purification and preparation for trade purposes. Graphite deposits are not common; they are found, it is said, only where Carbonaceous rocks are in direct contact with igneous rocks. Elaborate machinery is not required in mining it; the chief difficulty is from its greasy, slippery nature, which makes very careful timbering and handling necessary. It is much used in the production of non-corrosive paints and crucibles for smelting gold, in iron foundries, and for lubricants and household purposes. The price here of graphite paints, containing about 35% of pure graphite, has been as high as \$390 a ton; graphite for molding purposes has brought as much as \$224 a ton in the Australian foundries, and some of the crucibles for gold have cost \$975 a ton.

A recent official report on the Mount Morgan mine states that the new underlie shaft is 119 feet deep. The country is treacherous and the work has to be done with care. Two diamond drills are in commission and 900 feet of drilling was accomplished during November. In the 750-foot level the chamber in the copper ore is rapidly increasing. This cut is now in about 250 feet in a solid body of ore. The chamber is being widened and wide drives are being cut into the sides to have a number of faces ready for an increased force. In the 850-foot level driving is being carried on, but no ore has been mined at this depth. In driving along the ore body at this level pay ore was touched at several points.

The new steam shovel has now been operating in the open cut for a month. Its capacity is from 10,000 to 12,000 tons of overburden monthly. The returns from the Mount Morgan mine for November show that 12,508 ozs. 5 dwts. of gold was won from 14,522 tons of stone, and that for three months 11,191.65 tons of old tailings have been retreated for a yield of 1211 ozs. of gold. The copper precipitating canals caught 25 tons 1 cwt. of copper precipitates, containing 19 tons 10 cwt. 3 grs. of metal. The copper smelter for the month produced from 740 tons of copper ore, and by-products mixed, 70.34 tons of matte containing 32.99 tons of metal, and 589 ozs. 19 dwts. 13 grs. of fine gold. The value of the output for the month from the mine aggregates \$58,412, calculating copper at \$62 a ton, local value. The 740 tons of copper ore put through, the smelter yielded 4.45% of metal. The copper ore treated yielded 14 dwts. 14 grs. of gold to the ton, in addition to its copper contents.—The Sovereign (New Clanricard) is being developed. The 91 tons recently forwarded from this mine to Aldershot yielded 3 ozs. gold and 5% copper per ton.—Notwithstanding the drawbacks experienced at the Dee placer rush, owing to the want of water and the consequent stoppage of cradling, the output of alluvial for the month aggregated 467 ozs., to which total Crawford and party contributed 195 ozs., Cato & Townsend 118 ozs., Sutherland 29 ozs., and Nunn and party 28 ozs. A good many claims within the big nugget area have yet a considerable quantity of ground to test, but a number are nearly worked out, and unless something new is found in the meantime the number of men at present working is sure to decrease during the next few months.

#### Western Australia.

(Special Correspondence).—The Tower Hill Gold Mines at Leonora, in the Malcolm district, has a 40-stamp mill and filter press cyanide plant. R. B. Lamb, formerly in charge of the Westralia Waihi Gold Mines at Davyhurst, is superintendent. Kalgoorlie, Dec. 15.

The report of the Department of Mines of Western Australia for 1903 shows the total mineral output to be worth £8,971,937. The gold output was 2,064,801 ounces, valued at £8,770,719; 133,427 tons of coal were raised, valued at £69,128; 817 tons of block tin, valued at £55,890; 20,526 tons of copper ore, valued at £36,541; 168,113 ounces of fine silver. The dividends paid during the year amounted to £2,024,152. The number of men engaged in gold mining was 20,716; the value of gold produced per man was £423.37.

#### BRITISH COLUMBIA.

The Fort Steele Prospector estimates mineral production of British Columbia in 1904 as follows:

	Ounces.	Value.
Gold .....	313,185	\$6,264,000
Silver .....	3,505,805	1,898,000
	Pounds.	
Copper .....	36,684,580	4,540,000
Lead .....	37,000,000	1,415,000
	Tons.	
Coal .....	1,668,000	5,004,000
Coke .....	272,400	1,362,000

The approximate mineral output of British Columbia for 1904 is as follows:

Gold .....	\$ 6,400,000
Silver .....	2,200,000
Copper .....	4,600,000
Lead .....	1,500,000
Miscellaneous .....	600,000
Total mineral production other than coal .....	\$15,300,000
Coal and coke .....	4,470,000
Total .....	\$19,770,000

#### Boundary District.

Rich ore has been struck in the Paymaster fraction, near Midway, by G. R. Naden. — There are fifty men working the mines on the West Fork. The shippers are the Sally and Rambler. The Carmi stamp mill is in operation. — After a brief shut down, owing to lack of electrical power, the second furnace at the B. C. Copper Co.'s smelter has been blown in.

The British Columbia Copper Co. at Greenwood has its briquetting plant completed and is reducing its \$100,000 dust pile. They have placed a pumping plant on the artificial lake back of the smelter, created by damming the water of Copper creek with hot slag. This, in connection with its large steam plant, will always constitute a reserve power in case of emergency arising from failure of electric power.

T. H. Rea, superintendent of the Hesperus Gold-Copper Mines Co., says that the company has put in a 5-drill straight line air compressor and has spent about \$10,000 in improvements, including hoarding and bunk houses at the mine on Fourth of July creek, 3 miles from Grand Forks. The tracks of the Great Northern extension to Phoenix are within 1500 feet of the mine, with which it is connected by a good wagon road. A new working tunnel, down the hill to strike the ore body 275 feet deep, is in 250 feet and ore has been encountered.—The Granby smelter is running five furnaces and treating over 10,000 tons a week.

The Granby Con. M., S. & P. Co. intend to put in two more blast furnaces. The Granby smelter has six furnaces at present and is smelting 50,000 tons of ore per month. These six furnaces are all 160x42 inches at the tuyeres. The two new furnaces are to be 207 inches long and 48 inches wide at the tuyeres. This will bring the smelter capacity up to 70,000 or 75,000 tons per month and will increase the copper production. The entire smelting system is being remodeled on a new plan introduced and tried by General Superintendent A. B. W. Hodges. The furnaces will be charged by an automatic charging car, which will take the ore direct from the ore bins and place it in the furnaces. The new furnaces and other equipment, including the blowers and motors and a large brick stack and extension for the flue chamber, will be ready by July 1. The converter plant is also being doubled.

#### Lardeau District.

The Eva mill at Camborne has been started. The plant contains a rock crusher, two 5-stamp batteries, 1000-pound stamps, sizers and four Frue vanners. Water

power under a 400-foot head from Pool creek is used to run the mill. A 4200-foot tramway carries the ore from mine to mill. It is reported that the Eva Gold Mines Co. will put in an air compressor.

#### Rossland District.

The Evening-Eureka group, near Rossland, is bonded to the Le Roi No. 2 M. Co., which is developing it. On the Evening a small compressor plant has been put in and a three-compartment shaft is being sunk. The three-compartment shaft on the Eureka has reached a depth of 165 feet, and sinking continues with three shifts and two machine drills. At the 160-foot station a cross-cut has been started.

#### Southeast Kootenay District.

The Sullivan M. Co. is having a 250-ton lead smelting furnace built at Marysville, making three furnaces in all. They are also building a 250 ton converter of the Haberlin type to reduce the amount of sulphur in Sullivan ore. The converter will be used as an experiment and, if satisfactory, another one will be installed. The Sullivan smelter is being fully equipped. F. D. Weeks has charge of the smelter. Water for power is flumed from Mark creek.

#### CANADA.

The report on the mining industry of Canada by the director of mines shows the total mineral products of the year to be worth \$12,870,593, and the wages paid amounted to \$4,222,386. Of the total value, \$7,628,018 represents products of the non-metallic class and \$5,242,575 metallic products. The total production of gold was 10,383 ounces, valued at \$188,036; the industry gave employment to 493 persons, who were paid in wages \$245,490. Including the cost of supplies it required an expenditure of almost \$2 to extract \$1 worth of ore. The same story is told of silver mining; the total quantity produced was 16,688 ounces, valued at \$8949, and the wages paid out, \$8000. The production of lead was still more unprofitable, although restricted. The amount mined was 25 tons, valued at \$1500, at a cost of \$5189. Copper and nickel properties on the whole gave excellent returns. The value of the products was \$3,215,794 and the wages paid aggregated \$872,302, leaving a large margin for supplies and a satisfactory profit. In the non-metallic class a good showing is made by petroleum and cement. The wages paid for the production of petroleum amounted to \$165,700, while the value of the product was \$1,586,674.

#### MEXICO.

The following statement shows the dividends paid by various Mexican mining companies during December, 1904: Dos Estrellas, \$90,000; Santa Maria de la Paz, \$72,000; Santa Gertrudis-Guadalupe, \$60,000; San Rafael, aviadoras, \$33,600; Real del Monte, \$25,540; Morias de Bajan, \$20,000; Soledad, aviada, \$19,200; Esmeralda, Matehuala, \$17,250; Hacienda La Union, \$15,000; Santa Maria de Guadalupe, \$12,500; Victoria, San Luis Potosi, \$12,500; Haciendas San Francisco, \$12,000; Carmen, Pachuca, \$11,000; San Rafael, aviada, \$9600; Sorpresa, aviada, \$4800; Hacienda B. de Medina, \$3000; Turquesa, preferred, \$750; total, \$419,010.

#### Chihuahua

The Rosario M. Co. of Guadalupe y Calvo will add forty stamps to its mill. J. A. Peahody of Fort Worth, Texas, is superintendent.

The stockholders of the Descubridora M. & D. Co. and the El Rayo M. Co., in the Las Azules district, near Parral, have decided to build a 100-ton plant as soon as experiments are completed showing the plant best suited to the treatment of the ore. G. J. McCarty of Minas Prietas, Sonora; R. I. Howitt and C. Crowell of Monterey; W. B. Cloete of London; H. Howitt of Canada and B. Peterson and J. F. Johnston of Parral are interested.

The Tecolotes mill of the Guggenheim Exploration Co. at Santa Barbara has resumed operations. Since closing down a year ago the arrangement of the power, tables, etc., has been changed.

#### Durango.

A preliminary survey is being run for a railway from Santiago Papasquiaro on the Tepichuacnes branch of the International railroad and San Andreas.

#### Guanajuato.

The Mitchell M. Co. has shipped to Acapulco, Mexico, materials for constructing a 250-ton smelting plant, at La Dicha, and will put in a larger plant. G. Mitchell is president of the company.

Mining machinery is to be bought for the Poder de Dios mine. J. E. Swain of the City of Mexico is interested.

#### Guanajuato.

The Guanajuato Con. M. & M. Co. is the largest now operating in the district. It has a 60-stamp mill and a number of cyanide tanks, and owns a controlling interest in the Carmen-Guanajuato Co. The Guanajuato M. and R. Co. has prepared plans for a custom mill which will also treat the ores of the company's property. The Guanajuato River M. Co. has machinery at work on the head of the Guanajuato river to recover the silver from the tailings which were dumped into it during the 300 years of the bonanza era of the district. Many small properties are waiting for the erection of custom mills to resume work.

#### Jalisco.

The manager of the Santo Domingo mine at Etzatlan is experimenting as to the best method of treating the ores and will put in a milling plant.—The Agua Blanca copper mine at Etzatlan is to be equipped with a concentrating plant. W. N. Cummings is manager; it is owned by the Dwight Furness Co. The vein carries argentiferous and auriferous copper ores and argentiferous lead ores.

#### Lower California.

J. B. Runk of Jacalitos, 50 miles north of Alamo, and J. P. Bull of San Jose, are working the Mai Maran mine at Jacalitos, and have sunk the shaft 55 feet and run a 60-foot drift. Additional machinery will be purchased.

#### Mexico.

The shaft work at the San Patricio mine at El Oro has stopped owing to the difficulties presented by a body of rock that has been encountered, and, apart from the pumping of the shaft, operations are suspended. Ma-

chinery for diamond drilling has been set up and drilling started. Manager F. J. Graham is in New York City.

#### Oaxaca.

The Compania Compradora y Beneficiadora de Metales, in which C. P. Mena and A. L. Charlot are part owners, will put up a 25-ton milling plant at Tlacolula.

#### Sonora.

(Special Correspondence).—On the Americus copper mine, adjoining the Sierra de Cobre property, near Cananea, a 200-foot shaft has been sunk and work has begun on a double-compartment shaft. — R. K. Clancy of Detroit, Mich., has purchased the Eva, El Eden, Serro Finobella and Cinco Senores mines, 50 miles from Cananea, in the Picacho district. — R. Templeton of Magdalena district has denounced 15 pertenencias in that section, upon which is a shaft 130 feet deep.—The Chimata mine, 150 miles south of Cananea, in the Huepac mountains, is owned largely by F. J. Toussaint of Wisconsin. — On La Plomosa property, 5 miles from Huepac, a large smelter is being built. R. Graham is superintendent. — The smelter being built on the Transvaal mine, near Arizpe, will begin operations July 1.

Cananea, Jan. 30.

The Dea Gold M. Co., L. Padres manager, is developing a gold mine 1 mile from La Colorada.

The Coast Line C. Co., with office at La Calera, Altar, Sonora, have put reduction machinery on the El Oro mine, east from Poza. J. T. Cave has been re-elected president, J. A. Elliott secretary and treasurer, and J. Henderson manager.

#### PHILIPPINE ISLANDS.

F. L. H. Kimball is putting up a Ridsdon bucket dredger on the gravel property of the Philippine M. Co. on Masbate island.—The Philippine G. M. P. & D. Co. is putting in a Hendy 10-stamp mill at Camp Robinson, 31 miles from Kias, Benguet. J. F. Kemp of Washington, D. C., is president, W. S. Gray of San Francisco, Cal., secretary and manager, and H. E. Robinson superintendent.

#### SOUTH AMERICA.

##### Bolivia.

T. Hooper reports to the British Consul at La Paz that the department of Oruro, on the Bolivian plateau, has produced silver ores since the Spanish conquest, and lately tin; the latter has assumed more importance. The principal silver mines are at Oruro and are worked by La Compania Minera de Oruro and La Compania Minera de San Jose. Oruro is connected with the port of Antofagasta by a railway 574 miles long. The ores are worked for silver and tin. A certain amount of oxidized ores from the near outcrops are worked for tin, but the bulk of the mineral comes from the sulphide zone and consists principally of a mixture of iron pyrites, antimonial minerals, tin oxide, varying quantities of the mineral andorite, or sunnite—a sulpho-antimonide of lead and silver, which, pure, contains over 10% of silver—and occasionally a little stannite and galena. These ores are sorted at the mines and then sent by rail to the reduction works. The Compania Minera de Oruro, at Machacamarca, has a 50-ton plant, 25 kiloms. from Oruro, where the ores are treated by hypsulphite lixiviation and the silver sulphide shipped to Europe. The tin oxide is taken out by concentration, raised to about 60% metallic tin and shipped to Europe. These ores come from the mines called Socavon de la Virgen and from those of the Compania Minera de Itos, controlled by the Compania Minera de Oruro. The ores from the San Jose mines, belonging to the Compania Minera de San Jose, are sent by rail to Poopo, 50 kiloms. from Oruro, where they are treated in the works of the Compania Beneficiadora de Poopo. The silver is extracted by lixiviation, but the tin is extracted and treated in water-jacket furnaces and sent away as bar. In the range of hills east of Poopo silver and tin are found and the Trinaeria mine is working now. The distinctive feature of the ore is a cylindrite or rylindrite, which assumes a peculiar cylindrical crystalline form, and contains antimony, lead, zinc, arsenic and silver, combined with sulphur. This ore contains as much as 3% silver, and, though found sparingly, is the mineral which mainly gives value to the ores. It is found associated with iron pyrites, zinchenide, a little tin and sometimes galena. These ores are treated by lixiviation and concentration in the Bella Vista works at Poopo. The other districts that produce tin, which, from this point of view, are more important than the above-mentioned places, are dealt with below. At Chualla Grande, 9 miles from Pazna on the Antofagasta Railway and 25 kiloms. from Oruro, the Avicaya, belonging to Abell & Co., the Tortoral mines and the Chunchu mines at Antequera send their concentrates, ranging from 65% to 73% metallic tin, to Europe. In the Huanuni district several enterprises are working tin lodes—the Huanuni Tin Co., T. Hermanos, A. Penny, J. Duncan and others. Lead, copper, zinc, bismuth, gold and antimony are found but are not worked.

#### Trade Treatises.

The Glohe Iron Works of Stockton, Cal., have issued an attractive description of the Truax automatic ore cars, in a well printed and nicely designed booklet. The text description is ably aided by good illustrations. A perusal of its pages gives an insight into the ease and speed with which ore and water can be handled.

Publication No. 117 of the Allis-Chalmers Co. of Milwaukee, Wis., describes their latest improvements in Gates rock and orebreaker. Style D is their most recent design for crushing from 2 to 200 tons per hour, and style F for laboratory crushing. Portable rock breaking plants are also illustrated. The fine halftones assist materially in aiding the argument of the text. The typographical appearance is well up to the high standard set by Allis-Chalmers' publications. The booklet contains valuable information to anyone interested in rock breaking.

## Personal.

W. H. KRITZER of San Francisco, Cal., is at Goldfield, Nev.

J. G. MATTES is manager of the Lucky Boy mine at Keystone, S. D.

A. H. GUNNELL has returned to Grants Pass, Or., from New York.

W. THOMPSON is manager for the Waterson gold mines at Ocampo, Mexico.

J. GROSS has been appointed superintendent of the Horseshoe mill at Terry, S. D.

THOMAS HARRIS, superintendent of the Keystone placers, near Telluride, Colo., is in Denver, Colo.

ALEXANDER VEITCH, superintendent of the Arizona Copper Co. at Clifton, Ariz., is in San Francisco, Cal.

N. W. PARLEE has left Rossland, B. C., to become superintendent of G. A. Longnecker's mine at Dillsburg, Pa.

H. SIMONS has been appointed superintendent of the Reforma mine and smelter at Campo Marado, Guerrero, Mexico.

A. R. WILFLEY of Denver, Colo., has returned there from an extended trip through Arizona and southern California.

E. B. VAN OSDEL has resigned as superintendent of the smelter of the Turk M. Co. at Deer Trail, Wash., and is in Seattle.

J. A. FARWELL, vice-president of the J. George Leyner Engineering Works Co., Denver, Colo., has returned there from Chicago, Ill.

J. F. KEATING, superintendent of the Butterfly-Terrible G. M. Co., near Ophir Loop, Colo., has returned there from Denver, Colo.

S. LEVY, of the Western Exploration Co., has succeeded A. E. Hyde, Jr., as manager of the Annie Laurie mine at Kimberley, Utah.

A. E. HYDE, Jr., has resigned as the manager of the Annie Laurie mine at Kimberley, Utah, and will develop his interests at Goldfield, Nev.

N. C. BONNEVIE, manager of the Denver Ore Testing & Sampling Co., Denver, Colo., has been in New York City and other Eastern points.

W. SAUNTRY, president of the Columbus Con. Co. at Deadwood, S. D., has been at the mines of the Yaqui Copper Co., in Sonora, Mexico.

L. D. SIVYER of Los Angeles, Cal., is engaged in professional examination of an ancient silver mine in Sonora, Mexico, for Michigan parties.

GEO. W. MYERS, Pacific coast representative of the Chrome Steel Works, has returned to San Francisco, Cal., from a business visit to southern California.

O. HENKEL, connected with the La Colorado M. Co., in Sonora, Mexico, has been made superintendent of the American M. Co., operating in Ecuador, South America.

J. J. MACDONALD has resigned as manager of the Seal of Gold M. Co. at Dale, San Bernardino county, Cal., to become general manager of the Mendoza Con. C. M. Co. at El Valle Perdido, Lower California, Mexico.

E. A. H. TAYS has resigned as manager of the mine and smelter of the Sociedad Minera y Fundidora at Maconi, Cadereyta, Queretaro, Mexico, to resume practice as consulting mining engineer at Fuerte, Sinaloa, Mexico.

J. E. HUBINGER, president, and F. D. Wetmore, a director, of the Arizona & Mexico C. Co., accompanied by W. E. Defty, engineer of the company, are visiting their property near Caborca, in the Altar district, Sonora, Mexico.

## Books Received.

"Forest Conditions in the Ahsaroka Division of the Yellowstone Forest Reserve, Montana," by J. B. Leiber, Professional Paper No. 29 of the United States Geological Survey.

"Report of the Department of Mines of Western Australia for 1903," gives a comprehensive statistical account of mining operations and production. As the government exercises control over the mines of Western Australia, the report contains much information not found in statistical American reports.

Bulletin No. 246 of the United States Geological Survey is entitled "Zinc and Lead Deposits of Northwestern Illinois, by H. F. Bain. It contains descriptions of the topography, geology and ore deposits of northwestern Illinois, with a discussion as to the origin of the deposits. The mines are found in Jo Daviess county, near Galena and Elizabeth, forming a portion of the upper Mississippi zinc and lead field, which lies mainly in Wisconsin, but includes parts of Illinois and Iowa. The region is one of unmetamorphosed, little disturbed, sedimentary rocks of Paleozoic age, and there are no igneous rocks in or near it. The ores are smithsonite, and zinc sulphide occurring in gash veins.

## Obituary.

O. C. BUCKBEE of San Francisco, superintendent of the Caylord mine, near Auburn, died of pneumonia January 28th at Auburn.

## Commercial Paragraphs.

ENGLEBACH & REYNOLDS MACHINE CO. have opened a machine shop at 1401 Blake street, Denver, Colo.

R. J. CORY, formerly manager of Allis-Chalmers Co.'s Denver branch, is now at 1750 California street, Denver, Colo.

L. M. WARD has been appointed manager of the Denver, Colo., office of the Crocker-Wheeler Co., at 525 Seventeenth St.

THE Wellman-Seaver-Morgan Co. of Akron and Cleveland, Ohio, and the Brown Hoist Co. of Cleveland, Ohio, have consolidated.

THE Mine & Smelter Supply Co., Denver, Colo., has appointed A. W. Sales their New York manager with offices at 42 Broadway, New York City.

THE Hydro-Carbon Manufacturing Co., Denver, Colo., W. Van R. Whitall, manager, will enlarge their plant for the manufacture of their brand of paints.

CLEMENT & STRANGE, engineers and contractors, have opened offices at 307 Dooly Block, Salt Lake City, Utah. The firm is composed of Harrison Clement, until recently with the Bingham Con. M. & S. Co. as mining and mechanical engineer, and V. P. Strange, consulting mining engineer and manager of properties in Goldfield, Nevada.

THE National Wood Pipe Co. of Los Angeles and San Francisco has made another shipment of 8-inch and 10-inch machine banded redwood water pipe to the Cananea Con. C. Co., Cananea, Sonora, Mexico, to supply concentrators Nos. 1 and 2 with water. This pipe is especially adapted for conveying water heavily charged with acids, minerals or alkalis.

THE S. H. Supply Co., Denver, report recent sales of a complete hoisting plant, with No. 7 Cameron sinking pump, to Old Mexico; a complete hoisting plant to Tin Cup, Colo., and a 10-stamp mill to Oregon. This company will shortly move their stock of mining machinery from Twenty-second and Larimer streets to Eighteenth and Lawrence streets, Denver, Colo.

BONNEVIE & LEE, managers of the Denver Ore Testing & Sampling Co., have dissolved partnership, E. A. Lee retiring. N. C. Bonnevie will have the management of the plant hereafter. The head office of the company will be retained at 527 Seventeenth street, Denver, Colo. The management expect to double the capacity of the testing works, corner Bryant and West Sixteenth avenue, Denver.

THE DeRemer Water Wheel Co., of Denver, has a contract with F. H. Sethman, Denver, Colorado, for six 32-inch DeRemer water wheels for Glenwood, Nevada. These six wheels will constitute two units of power of 350 H.P. each. Each battery will consist of three wheels on one shaft, and under an effective working head of 400 feet should develop a velocity of 600 revolutions per minute.

THE rock drill and air compressor trade was largely represented at a gathering of associates and friends of Mr. Geo. A. Howells at the office of the Rand Drill Co. in New York, January 5th—the occasion marking the twenty-fifth consecutive anniversary of Mr. Howell's connection with the company. During the afternoon Mr. Howells was presented with a handsome loving cup by the officials of the company.

THE Richards Rapid-Economy Stamp Mill Co., of San Francisco, Cal., has now in operation several of its 3-stamp mills which are reported as giving satisfaction. The manufacturers claim that they are crushing a much larger percentage of rock in twenty-four hours with the three stamps than is being done with an ordinary gravity 5-stamp battery, and with the use of less power, and exhibit testimonials of reputable mining men who have the mills in use.

THE Davenport Foundry & Machine Co., Davenport, Ia., report the following recent shipments: Slope haulage engine for Southwestern D. Co., Colgate, I. T.; two hoisting engines for Continental Coal Co., Nelsonville, O.; five sheave wheels to Minera de Penoles Co., Mapimi, Mexico; two 24x36 hoisting engines to Springfield Colliers Co., Springfield, Ill.; two 20x36 hoisting engines to Landis Mining Co., Landis, Pa.; two hoisting engines to Clover Leaf Coal Co., Dugger, Ind.

ON account of the similarity and conflict in names of other concerns, the Second-Hand Machinery Co., which was organized a short time since and consolidated the S. S. Machinery Co., Tom Crow Machinery Co. and Machinery Supply & Implement Co., have changed their firm name to the Great Western Machinery Co., with offices at 1626-1638 Blake street, Denver, Colo. The officers are: H. Stewart, president and treasurer; T. Crow, vice-president and superintendent; Morris Block, secretary; D. C. McNerny, general manager.

THE following is a list of "Hornsby-Akroyd" oil engines recently installed or being constructed by the De La Vergne Machine Co. of New York: U. S. Navy Department, Wireless Telegraph Station, two 50 H. P.; Indianapolis Pipe Line Co., Geneva, Ind., one 32 H. P.; Ohio Oil Co., Findly, Ohio, one 25 H. P.; C. M. Holbrook, Oil City, Pa., two 32 H. P.; The Charles Mills Supply Co., New York City, one 13 H. P., one 7 H. P.; E. C. Bumiller, Iquique, Chile, two 4 H. P.; Thirteenth Regiment Armory, Brooklyn, N. Y., one 20 H. P.; Honolulu Iron Works, one 32 H. P.; Balbach Smelting & Refining Co., Newark, N. J., one 50 H. P.; C. E. Hewitt & Co., New York City, one 125 H. P.; Boston Light-house Department, two 4 H. P.; Bristol Electric Light Co., Bristol, N. H., one 50 H. P.; Armour Car Lines, Chicago, Ill., two 125 H. P.; Thos. Stephens & Sons, Ltd., Albany, N. Y., one 16 H. P.; Remington Machine Co., Wilmington, Del., one 14 H. P.; Lighthouse Department, Tompkinsville, S. I., two 13 H. P.; Light-house Department, Milwaukee, Wis., four 16 H. P.; The Andrews-Doron Co., Los Angeles, Cal., one 50 H. P., two 125 H. P.

## Latest Market Reports.

SAN FRANCISCO, February 3, 1905.

### METALS.

SILVER.—Per oz., Troy: London, 27½d (standard ounce, 925 fine); New York, bar silver, 60½c, refined (1000 fine); San Francisco, 60½c; Mexican dollars, 51c, San Francisco; 47½c, New York.

COPPER.—New York: Standard, \$15.50; Lake, 1 to 3 casks, \$15.50@15.50; Electrolytic, 1 to 3 casks, \$15.67½; Casting, 1 to 3 casks, \$15.25. San Francisco: \$16.00. Mill copper plates, \$17.00; bars, 18@24c. London: £67 17s 6d spot per ton.

The copper market remains firm, with a slightly higher price both in New York and London. Electrolytic is quoted at \$15.67½—the highest price since the recent rise commenced. It is said that producers are sold up close to their output and, in view of this fact, it is not likely that prices will be lower for a time.

LEAD.—New York, \$4.55; Salt Lake City, \$3.50; St. Louis, \$4.12½; San Francisco, \$4.50, carload lots; 4½c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5½c; pig, \$4.85. London: £12 15s 6d long ton.

SPELTER.—New York, \$6.30; St. Louis, \$6.30; London, £24 15s 6d ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

TIN.—New York, pig, \$29.65@30.00; San Francisco, ton lots, 30c; 500 lbs., 30½c; 200 lbs., 30½c; less, 31c; bar tin, 31½c, 32½@35c. London, £131 12s 6d spot.

PLATINUM.—San Francisco, crude, \$18.50 ½ oz.; New York, ingot, \$19.50 ½ Troy oz. Platinum ware, 75@82c ½ gram.

QUICKSILVER.—New York, \$40.00@41.00, large lots; London, £7 12s 6d; San Francisco, local, \$38.00 ½ flask of 75 lbs.; Denver, \$45.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 31½c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 19.50c; San Francisco, Plumbers', 100-lb. lots, 16.25c.

ZINC.—Metallic, chemically pure, ½ lb., 50c; dust, ½ lb., 10c; sulphate, ½ lb., .04c.

NICKEL.—New York, 55@60c ½ lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c ½ lb.; 100 lbs., 35c; 1000 lbs. 34c; ton lots and over, 33c, Pittsburgh. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburgh.

### STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$16.85@17.10; gray forge, \$16.85; San Francisco, bar, 3c ½ lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburgh, \$25.00@26.00; open heartb billets, \$25.00@26.00; San Francisco, bar, 7c to 12c ½ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, ½ c ½ lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, ½ c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

LUMBER.—(Retail): Pine, ordinary sizes, \$24.00@25.00; extra sizes higher; redwood, \$28.00@30.00; lath, 4 feet, \$4.50@5.00; pickets, \$21.00; shingles, \$2.50 for No. 1 and \$2.25 for No. 2; shakes, \$13.50 for split and \$15.00 for sawed; rustic, \$28.00@35.00.

NAILS.—This week the basic prices are: Wire, \$2.77; Cut, \$3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, \$3.35; Cut, \$3.55; 10d to 16d, Wire, \$3.45; Cut, \$3.35; 8d, Wire, \$3.50; Cut, \$3.50; 6d and 7d, Wire, \$3.60; Cut, \$3.60; 4d and 5d, Wire, \$3.70; Cut, \$3.70; 3d, Wire, \$3.85; Cut, \$3.85; 2d, Wire, \$4.10; Cut, \$4.10. Special rates for carload lots.

LIME.—Santa Cruz, \$1.25 country, \$1.25 city ½ bbl.

CEMENT.—Imported, \$2.15@2.65 ½ bbl.; California, carload lots, \$2.10 f. o. h. at works; small lots, \$2.40 ½ bbl. in sacks, 4 sacks to bbl., 10c for each sack returned.

### GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 8½c; Hallett's, 8½c; San Francisco, 1000-lb. lots, 9c; 300@500-lb. 9½c; 100-lb. lots, 10½c.

COAL.—San Francisco, coast, yard prices: Wellington, \$8.00; Seattle, \$6.50; Coos Bay, \$5.50; Southfield, \$8.00. Cargo lot, Eastern and foreign: Wallsend, \$7.50; Brymho, \$7.50; Pennsylvania, hd., \$14.00; Scotch, \$8.00; Cumberland, \$13.00; Cannel, \$8.50; Welsh Anthracite, \$13.00; Rock Springs, \$8.50, long ton; Colorado Anthracite, \$14.00. Coke, \$10.50 per ton in bulk, \$13.00 in sacks; Sunnyside, \$8.50, long ton.

OILS.—Linseed, hoiled, hbl., 55c; cs., 60c; raw, hbl., 53c; cs., 58c; Lucol oil, hoiled, hbl., 50c; cs., 55c; raw, hbl., 48c; cs., 53c. Kerosene—Pearl, per gal., 19c; Astral, 19c; Star, 19c; Extra Star, 22c; Eocene, 21c; Elaine, 25c; Water White, in bulk, 12½c; Mineral Seal, iron hbls., 18c; wooden hbls., 20c; cs., 24c; Mineral Sperm, cs., 26½c; Deodorized Stove Gasoline, hulk, 16c; do., cs., 22½c; 80° Gasoline, hulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in hulk, per gal., 13c; do., in cs., 19½c; Lard Oil, E. W. S., hbl., 75c; cs., 80c; Neats-foot Oil, pure, hbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 63c; Bleached, do., 57c; Whale Oil, cs., 52@57c.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1\*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1\*\*, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2\*\*, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2.00 per keg.

CAPS.—3x, \$5.50@6 per 1000; 4x, \$6.50@7; 5x, \$8@8.50; Lion, \$9@9.50, in lots not less than 1000.

FUSE.—Triple tape, \$4.00 per 1000 feet; double tape, \$3.50; single tape, \$3.10; Hemp, \$2.75; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11c ½ set; 14 oz., 40s., 9½c.

## Powder in Mines.

The disastrous results often attending the storing of large quantities of dynamite in mine workings has been again fearfully demonstrated at the North Kearsarge copper mine, one of the Osceola Consolidated Co.'s mines near Houghton, Mich., where on the 8th inst. a quantity of nitro powder, stated to be 10,000 pounds, which was stored in a magazine on the eighth level of the mine, was exploded in some unknown manner. Several miners were killed outright and others are supposed to have been suffocated by the deadly fumes resulting from the explosion, and which completely filled the mine workings. That portion of the mine in the vicinity of the explosion is a complete wreck. Number 3 shaft, near which the explosion occurred, is 2280 feet deep, opening a large area of rich ground. The workings connect with the Wolverine mine on the north, and this shaft is the third from end line. Forty machine drills are employed in this mine, and the amount of powder required daily is large, probably not less than 1000 pounds, as from 300 to 400 holes or more are drilled daily. This may, in a measure, be considered an excuse for carrying so large an amount of dynamite in the mine workings, particularly at this season of the year when the temperature is very low in the Lake region, and frozen dynamite is useless, though even more dangerous in thawing than it is at normal temperature. Still it seems that the large amount of powder required might have been distributed to several stations. But if it were in ten different places there would still be sufficient in each magazine to do serious damage to the mine in event of explosion. The most regrettable thing in

The Sandstorm Mine, Goldfield District, Nev. (See page 84.)

connection with this disaster is that the lives of at least five men, and possibly many more, were sacrificed. The man in charge of the powder magazine was instantly killed, and probably he was the only one who could have known the immediate cause of the explosion. The Osceola Company have been making extensive improvements on their large property and have one of the most valuable as well as one of the most thoroughly equipped and best managed properties in the Lake copper region, and it seems unfortunate that the danger ever present in the storage of such large amounts of dynamite in the mine workings should not have been appreciated, and a separate place provided for it at a distance from the workings, accessible to those only whose

duty it was to distribute the powder. It is a notorious fact that constant contact and familiarity in handling dynamite renders men careless, and it often seems that the larger the amount handled the more likely those handling it are to become careless. Undoubtedly this disaster will result in the enforcement of strict regulations concerning the storage and distribution of dynamite in underground mine workings, not only on Lake Superior, but throughout the world.

THE American Institute of Mining Engineers has made an innovation in the publication of advance sheets of papers written by its members. Hereafter these sheets will be issued in the form of a bi-monthly bulletin, bound in paper. The transactions are copyrighted, something which has never been heretofore done. The object in making this change is to take advantage of the postal laws, and thus reduce the cost of sending out the large volume of literature issued by the Institute.

ALTHOUGH the mining industry on the Rand in South Africa has been established for eighteen years, it is only within the past few months that an attempt has been made to crush the ores of the banket by any other means than stamps. Recently a vertical roller mill—similar in operation to the Chile mill—has been set in operation. How it will be received as a competitor to stamps, and what comparative record can be made with it, has not yet been determined.

COAL MINING COMPANIES almost universally employ steam for motive power, presumably because of its cheapness. The coal costing a minimum price. The Lackawanna Coal Co. at its Truesdale colliery at Wilkes-barre, Pa., is about to inaugurate an innovation by installing a water power plant to operate the machinery of its mine and breaker. Cost of power will be reduced 90%.

Tonopah, Nev., in January, 1905. (See page 84.)

## State vs. Federal Mining Law.

In a recent suit in Nevada, Judge Hawley held that the law of Nevada requiring the recording of mining notices is not sound law and not necessary, as a locator can hold his claim by merely performing the annual assessment required by the Federal law, which the court considers to be the best evidence that the claim holder intends to comply with the law.

This decision is of unusual interest in view of that recently handed down by Justice Brewer of the United States Supreme Court, reference to which was made herein in the issue of February 4th, and in which Justice Brewer upholds the right of the several States to enact mining legislation, not conflicting with the laws of the United States. This was in a suit in Montana, in which the constitutional right of the State to make supplementary mining laws was questioned. The State of Nevada has a code of mining laws, and one of the provisions of this code is as follows: "Within ninety days of the date of posting the location notice upon the claim, the locator shall record his claim with the district recorder and the county recorder of the mining district or county in which such claim is situated by a location certificate, which must contain: First, the name of the lode or vein; second, the name of the locator or locators; third, the date of location and such description of the location of said claim, with reference to some natural object or permanent monument as will identify the claim; fourth, the number of lineal feet claimed in length along the course of the vein each way from the point of discovery, with a width on each side of the center of the vein, and the general course of the lode or vein as near as may be; fifth, the dimensions and location of the discovery shaft, or its equivalent, sunk upon the claim; sixth, the location and description of each corner, with the markings thereon. Any record of the location of a lode mining claim which shall not contain all the requirements named in this section shall be void. All records of lode or placer mining claims, mill sites or tunnel rights heretofore made by any recorder of any mining district or any county recorder are hereby declared to be valid and to have the same force and effect as records made in pursuance of the provisions of this act. And any such record or copy thereof, duly verified by a mining recorder, or duly certified by a county recorder, shall be prima facie evidence of the facts therein stated."

In this section of the State laws the requirements are plainly set forth and a penalty provided for non-compliance, for the law says that any claim not duly recorded as required by this law shall be void. The decision of Judge Hawley, that the Nevada law was not good law, was probably rendered prior to the decision of the Supreme Court, or without knowledge of that important decision.

## The Drainage Tunnel in Colorado.

It is stated that Colorado legislators contemplate new legislation on drainage tunnels, in which it is contemplated to make the driving of drainage tunnels possible in the face of minority opposition. It is proposed to establish drainage districts through the medium of the courts. When one-half of the property owners control or own one-third of the property, they may petition the courts to establish a "drainage district." Then the court is to appoint a commission to make an examination and render a report to the court. Both sides to the controversy will have a hearing before the court. If it is decided to form a district, it is done by authority of the court, and the cost of such drainage works as may be made is assessed to all the property benefited by the tunnel. The value of drainage tunnels cannot be disputed, but the attempt to make a law of this character is new in mining legislation, though in particular cases, it seems reasonable that those who would derive benefit from such a tunnel should have some legal means of accomplishing their object in spite of opposition from a minority. The attempt to force a proposition through, however, is likely to result in strong opposition from those who do not care to share the expense, and before a law, such as contemplated will become of value it will have to stand the test of the courts, as all such legislation must. It is hopeful that the bill proposed will become a law and that those who realize the value of such a meas-

ure will be able to sustain it against any possible opposition. There doubtless are times when a mine in the vicinity of a tunnel would derive little apparent benefit from it, for geological or other reasons, and the assessment to such property would probably be entirely out of proportion to the possible benefits, but the proposed bill takes cognizance of such a possibility and provides for a proper adjustment of the matter by making such exception in favor of the mine in question as the committee of engineers may find proper and equitable. This phase of the bill should relieve it of strong opposition from any quarter.

## Important Supreme Court Decisions.

The United States Supreme Court has recently rendered some decisions on mining law which are destined to have a marked effect upon the development of certain mining districts. One of the most important is in the case of the Creede Mining Co. v. Uintah Co., in which case the Supreme Court on January 29 affirmed the decision of the lower court, and held the following propositions:

(1) A patent to a lode is not conclusive as to the date of its location, except that owners of surface conflicts who have failed to adverse, are therefore adjudged to be junior to the patented lode.

(2) Prior to patent a lode claimant has a vested right only in the surface and the vein apexing therein, and therefore a tunnel claimant prior to patent of the lode may run underneath the surface of the lode claim.

(3) A tunnel claimant who has not discovered a lode is not required to adverse a lode application, but may after patent show that the tunnel site was prior in date to the lode claim.

The courts have repeatedly held that one claim holder may not pass through nor enter within the lines of an adjoining claim for any purpose whatever, except in the pursuit of the vein on its dip. In the above ruling the United States Supreme Court now makes a distinction between patented and unpatented mineral claims, and says a tunnel claimant may enter and run beneath the surface of a contiguous locator, prior to patent. If this doctrine were advanced by a lower court a reversal would naturally be anticipated, but when a decision issues from the Supreme Court of the United States, there is no appeal to a higher tribunal. The full text of the decision in the above case is not yet at hand, and the theory of the stand taken by the court is not known, but in many regions where tunnel cases have been numerous, the decision will create astonishment, and may alter the trend of subsequent events in mine development.

CONGRESS has taken about 7000 square miles from northern Arizona and added it to Utah, all that remains to complete the transaction being the signature of the President. The territory in question is all that portion of Arizona in Mohave and Coconino counties lying north and west of the Colorado river. The Grand and Marble canyons form a commercially impassable barrier between the country lying to the north of the river and that on the south, and it naturally attaches to Utah, although Arizona's citizens vigorously objected when an attempt was made to annex this section to Utah two years ago. In the present instance it seems to have been an oversight in the statehood bill in which Arizona and New Mexico are concerned. There is little mineral wealth developed in the section in question, there being some copper ore deposits of a superficial character in the Permian formation and some iron in the area. It is for most part heavily timbered and springs of water are comparatively abundant. It will become a valuable addition to Utah, though, under the peculiar conditions attending the transfer, costing Utah nothing.

THE desert region of California has thus far not offered much inducement to practical oil men, as neither the geological nor commercial conditions are favorable; but, notwithstanding this, thousands of acres of these desert valleys and mountains are located as oil lands. Every outcrop of rock is either of volcanic origin or it belongs to crystalline schists, in which there is no possibility of finding oil, and yet derricks have been built and drilling outfits put in to bore for oil where no oil exists.

IN the Idaho Legislature an attempt was recently made to create an eight-hour day for miners, but the bill, through the influence of the miners themselves, was defeated. It was thought the passage of such a bill would result in destroying the present peaceful conditions, and that a cut in wages would be made should the bill become a law. It was believed to be good business policy to let well enough alone.

THERE are many things in the methods of working coal mines and in surface equipment which might be adopted with advantage by metal mines, where condition warrant it, but they are seldom seen in practice. There is more in common in the two classes of mining than is generally supposed by those who are familiar with only one or the other kind of mine. The drainage methods of coal mines in particular could, in many places, be applied in metal mines and effect marked economy, but metal miners are inclined to follow rather closely the practices and traditions of the past, and do not think of looking to coal miners for instruction or hints.

THE uncertainties which lie in the path of the leaser were fittingly illustrated in the experience of the leasers on the Gold Coin property in the Cripple Creek district recently. For months they had toiled earnestly in hope of rich reward, but struck nothing of importance until the last shift, when a round of holes opened up a vein of bonanza ore. The company gave the leasers three days in which to make what they could out of the strike. It is these uncertainties which lure the sanguine miner. He believes in his luck and is confident of his ability, and often he is willing to "take a chance" where there is nothing material to guide him other than his "nose for ore," and he goes after it, and fortunately for him in most instances he finds it, but in the case above cited, rather late. This will no doubt give the leasers confidence and they will be willing to try their fortune once more, hoping that the reward, which they deserve, will not be so long delayed next time.

## CONCENTRATES.

USE high-power explosive to break your rock flae and lessen the work of your rock crushers.

TOO HIGH a heat in cupellation will result in losses both from volatilization and from absorption.

SLAGS from the assay furnace should be kept out of the fuel, as they will soon destroy the furnace linings.

STAINS can be removed from marble switchboard panels by applying a mixture of chloroform, benzine and plaster of paris.

CRYSTALS of litharge form in cupellation between 625° C and 800° C. To avoid silver loss the cupelling temperature should be kept within these limits.

IN sampling a mine, samples should be taken at intervals of not less than 10 feet, and where values are high and somewhat erratic at every 5 feet, with duplicates of each.

ONE HORSE POWER should be derived from each mine's inch under a pressure of about 485 feet, if the pipe line is over 10 inches diameter and not over 1 mile in length.

TAILINGS may be lifted a distance of several feet by means of a jet of water under pressure—a modification of the hydraulic elevator. The principle in each case is the same.

THE purchase of any mining machinery carries with it the right to repair such machinery and replace the worn parts until the essential original parts have disappeared.

STEAM STAMPS of the type in use at the Lake Superior copper mines have been changed from year to year. Twenty-five years ago the maximum capacity was 125 tons daily; now it is 500 tons or more.

THE Alaska-Treadwell mine crushes about 2600 tons of ore daily. About one-half of the values are obtained in the form of amalgam and the other half as concentrates, which constitute 2.3% of the ore.

STEAM SHOVELS are extensively used in the open pits of iron mines in Minnesota and Michigan, and recently they have been introduced in several gold and copper mines, underground, in Australia and British Columbia.

IF the compressor valves refuse to operate, it is probably due to the formation of some gummy substance. Use kerosene, turn the valves a few times by hand and the trouble is usually at an end. If not, call a machinist.

ALL efforts to introduce silica to converter charges by other means than that derived from the linings has proved futile. Pulverized quartz has been fed with the matte, and the sand came to the surface and floated on the molten metal.

IN coal mines the regulations usually require that not less than 100 cubic feet of fresh air per minute be blown into the mine for each man employed in the underground workings. In metal mines the amount necessary is usually much less than this.

A PHENOCRYST is a large well-formed crystal of any mineral which appears in the mass of a rock. The size is relative—thus a fairly coarse granite may develop large individual crystals of feldspar (phenocrysts). The rock is then granite porphyry.

CYANIDE OF POTASSIUM undoubtedly hardens copper amalgamated plates, but it also renders the mercury bright and active, and where the gold is susceptible to amalgamation good results should follow its use where it is necessary to crush in the battery.

TO GLAZE a crucible so that it will not absorb silver chloride or other substances, fill it with a boiling saturated solution of borax, let stand a few minutes, pour out and set the crucible aside to dry. This will also prevent metallic particles from adhering to it.

THE speed at which it is safe to hoist in shafts is limited only by the power of the engine, strength of the rope and condition of the shaft. The fastest winding is probably at the Kimberley diamond mines in South Africa and at some of the mines of Butte, Mont.

IN shaft sinking as many machine drills may be employed at one time as can be conveniently accommodated at the bottom of the shaft. It is not uncommon for two machines to be set on one bar. Often conditions are such that one chuck tender can attend to two drills.

A VENTILATING FAN provided with a by-pass system of piping and the necessary gates may be employed as either a blower or an exhaust fan. After shooting in the mine the fan should be run as an exhaust, which quickly removes the nitrous oxide and other gases,

when the air current may be reversed by a proper manipulation of the gates and fresh air blown into the mine workings. When this is done men may return in a few minutes to the face where the blasting has been done, without danger of inhaling powder gas.

WHEN drifting through ground that stands fairly well, but which gives indication of caving later, all spaces above the timbers and at the sides should be promptly filled as the work proceeds, as, if left until the ground caves, it may loosen the timbers and cause collapse.

ELECTRICITY is being employed constantly to a greater extent in mining and metallurgy. It is now being used to reduce iron ores. It is wholly employed in the manufacture of carborundum, and as a means of power electricity is finding a continually widening field of application.

THE loss of head in a 14-inch pipe line, due to friction, for each 100 feet of its length, is estimated to be equal to 3.13 feet at a velocity of 10 feet per minute. In an 18-inch pipe the loss, with the same velocity, is 2.14 feet for each 100 feet of line. The friction increases with the velocity of the stream.

THE cost of drilling artesian and oil wells varies greatly, depending upon the character of the formation through which the bore is driven. The price per foot ranges from \$1 to \$10 under ordinary conditions, depending on the size of the bore. Where great difficulties are encountered the cost will be higher.

FORMERLY double cone-shaped reels for hoisting engines were usually made with the smaller ends adjacent. Now the reverse is the case, the larger ends abutting, and usually the reel is a unit, though made in sections. The reason for this change is that it permits a better method of bracing and strengthening the reel.

TALC, pyrophyllite and serpentine greatly resemble each other and are sometimes difficult to distinguish from one another. Serpentine may be distinguished from talc or pyrophyllite (a variety of talc) by its complete decomposition in sulphuric acid; pyrophyllite is only partly decomposed by it and talc not at all.

THE main objection to breaking ore by calcining and quenching is the tendency to slime. This is some instances is no longer an objection, as there is a growing tendency to slime before cyaniding. It is a process often resorted to where rock is to be crushed in an arrastra, as it pulverizes more readily and amalgamates better.

THERE is no accurate method for the rapid determination of gold in cyanide solution that does not involve a fire assay. The most reliable and accurate method is the evaporation of 291.66 c.c. of solution and 20 to 50 gms. of litharge to dryness, and the subsequent crucible assay with a suitable flux. This method also determines the silver present.

A FLUME may be built on a much heavier grade than is usually given ditches, because of the tendency of the latter to cut on heavy grades, and a flume may also be built on a much lighter grade than a ditch to carry a given amount of water, because of the lesser amount of friction in the flume. Flumes, however, will average a heavier grade than ditches.

TIMBERS decay very slowly under water. Where the shaft has caved under water it will probably be found due to the fact that the lagging had decayed before the mine was flooded, and the pressure of the rock caused it to give way, when the rock, continuing to cave, removed the support from the main shaft sets and the entire framework of timbers caved in to the shaft.

THE Wolverine copper mine near Houghton, Mich., is one of the few large mines in the world where no timbers are used and so large a percentage of the ore recovered. The main stope is 1000 feet wide, 400 to 500 feet high (on the dip). The thickness varies somewhat. No filling is done, but the walls stand, with only a few scattering pillars to hold it. The angle of dip is about 40°.

IN ascertaining the head of water under which an orifice is discharging, measure from the surface of the water to the center of the orifice. This was the original idea of measuring the miner's inch of water; but, as the head was not uniform in the several districts, the Legislatures have adopted 1.5 cubic foot of water per minute as a standard miner's inch. This is 11.35 gallons per minute.

BOILER EXPLOSIONS are due to a number of causes—overpressure, defective plates, low water and suddenly introducing a quantity of cold water, and a faulty safety valve which fails to operate. These and other causes are responsible for boiler explosions. The cause can only be ascertained in most instances after the explosion, when it is not always possible to be sure of the cause.

THE two deepest vertical shafts in America are the Tamarack No. 5 shaft of the Tamarack Co. (4938 feet) and the Red Jacket shaft of the Calumet & Hecla Co. (4920 feet), in the Lake Superior copper region. The deepest vertical shaft in California is at the Kenaedy mine, near Jackson, in Amador county. It is 2700 feet deep, with a sump, and is soon to be sunk to 2850 feet.

There are several inclined shafts in California over 3000 feet deep, in the Grass Valley region, and the main shaft of the Congress mine, Yavapai county, Ariz., is over 3000 feet deep on the incline.

A TUNNEL is sometimes readily ventilated by merely placing a ventilating pipe along the roof and carrying the outer end to an elevation of several feet above the pipe at the inner end of the tunnel. The ventilation can be improved by connecting the outside pipe with a furnace or providing it with a wind sail. A water blast, when available, is also effective. The two latter schemes apply to shafts as well as to tunnels.

THE circular saws used in the timber framing shop may be run at a higher speed than flywheels of the same diameter. A 20-inch diameter saw may be run at a speed of 1900 revolutions per minute and a 32-inch saw at 1200 revolutions. A large saw, 60 inches diameter, should not run over 600 revolutions per minute. Some sawmill men believe a rim speed for circular saws of 10,000 feet per minute is not too great.

"CONCENTRATES" at this time has no knowledge of any one treating "black sand" by the cyanide process. It seems reasonable to expect that gold may be extracted from auriferous black sands if they be ground fine enough to render the gold subject to the attack of the solution. It is doubtful if a high percentage could be extracted without gridding, as the grains of iron would be impervious to the action of the solution.

CRUSHING ROLLS vary greatly both in diameter and width of face. The speed at which the rolls should be run cannot be predetermined, as this depends largely upon the character of the ore being crushed. There is much theoretical data upon the subject, but practical experience demonstrates that these formulas are not always dependable, and that because a set of rolls works well on one kind of ore is not a positive indication that they will do well at the same speed upon another ore.

THE gold-bearing lodes of the Kalgoorlie field, Western Australia, are very irregular as to size and value of the ore. In some places the lode splits up into two or more veins and in other places it is merely a lot of stringers and low grade. The vein sometimes swells to 30 feet or more and will carry average values of \$20 to \$35 per ton over the entire width. Near the surface of the Kalgoorlie mine, which below 300 feet was characterized by these features, the vein was 80 feet wide, averaging \$28 per ton.

THERE are 29,166 + ounces troy in one ton of 2000 pounds avoirdupois. Ores and base metals are weighed in pounds avoirdupois, gold and silver are weighed in ounces troy. The assay ton (A. T.) system was devised to avoid the tedious calculation necessary to find the number of ounces of gold or silver per ton of ore. One A. T. = 29,166 + milligrams or 29.166 grams, i. e., 1 milligram : 1 A. T. = 1 ounce troy : 1 ton av. Consequently the weight of a bead in milligrams is equal to the number of ounces troy per ton of ore.

THE difference in the value of mica for 1902 and 1903 was due to the closing down of the New Hampshire mines, also the majority of the mines in North Carolina. There were no mines in operation in New Hampshire in 1903 or 1904. The old Ruggles mine (which was formerly the greatest producer) being involved in litigation, was compelled to close down in 1900. In a mica mine it is difficult to give a definite figure as to how much plate mica it can produce, as there is a great variation in the production of each mine. A mine may produce a ton of plate mica with three men at work one month, while the next might not produce over 200 pounds.

WHEN designing a head frame for a shaft the position which the engine will occupy should be known in order that the direction of strain when hoisting may be determined. This resultant strain lies midway in the angle formed by the rope descending into the shaft from the sheave and that portion of the rope passing from the sheave to the drum of the hoist. The back braces of the head frame should be placed in such a position that this line of strain will fall just within the frame—between the back brace and the upright members supporting the sheave. The practice is to build with such heavy timbers that there is little danger of overturning or collapse, but by proper observance of the resultant strains expense in construction may be saved.

WHEN a shaft is sunk in the vein, or in the hanging wall near the vein, the mistake is often made of having too small a pillar of ore to support the shaft, with the result that a disastrous cave occurs. In a large ore body the pillar should extend not less than 50 feet beyond the shaft in both directions along the strike and across the entire width of the vein. It is not the danger of the pillar caving, but of the entire mass shifting, because of weakened support due to the removal of large quantities of ore from stopes adjacent to the shaft on several levels. In many cases it is desirable to leave a much larger pillar than that above suggested. The character of the vein material and of the walls, as well as the width of ground stoped, are the determining factors in making a decision on this point.

## Tonopah and Goldfield, and Their Rapid Development.\*

Written for the MINING AND SCIENTIFIC PRESS.

The rapid development of the new mining districts in Nye and Esmeralda counties in southern Nevada within the past four years is merely illustrative of the remaining possibilities of the present time. Many had entertained the idea that all the good mines had been discovered. That such is not the case is abundantly proven by the sudden rise of these new districts, in a region remote from railway facilities at the time of their discovery. When the first ore was found by J. L. Butler, in 1899, the nearest railroad station was at Sodaville, on the C. & C. railroad—60 miles across deep, desert sand, and little known water available in this distance. Within the time which has since elapsed, Tonopah has grown from an uninhabited desert valley to a town of nearly 5000 people, with many of the conveniences and even luxuries considered essential to comfortable existence in modern cities. The railroad has reached Tonopah, and already plans have been matured to extend it farther—to the newer camp of Goldfield. No mining district of the West has had more prompt and vigorous development than Tonopah. In many instances the mine equipment is modern and thoroughly up to date. Some of the properties had little or absolutely nothing "to go on" at the surface, except the geological indications, and, as the geology has come to be better understood, the prospecting has been conducted on more experienced lines and the probable extent of the payable possibilities greatly enlarged. At first there was a decided disposition to get as near the first discovery (the Mizpah) as possible, but the indications now are that there are other zones beyond the limits of the camp which deserve careful attention. When at a distance from the vein system which centers around the Tonopah Mining Company's property, of which the Mizpah is the principal mine, the prospector can be no longer guided by the probable strike and dip of those veins which have made Tonopah famous, particularly as much of the immediate vicinity is covered by a later deposit of andesite, or the desert wash. In such instances the miner goes back to first principles and looks for outcrops of mineral veins and ore deposits. Outcrops are not numerous, but such do occur. One of the accompanying illustrations shows the massive iron-stained outcrop of crushed and silicified andesite on one of the claims of the Archer group, 2 miles southeast of Tonopah. The Sierra Nevada Development Co. is opening this property, and have a shaft under way, and are also driving a tunnel. In the shaft values are reported.

The early prospectors in the Tonopah district soon appreciated the fact that to remain in that town and to carry their search no further would result in no good to themselves, and accordingly they pushed out in every direction—to Lone mountain and Gold mountain; to the old district of Reville, 50 miles east of Tonopah. Some went northward, toward Belmont, and new discoveries are reported in that direction. Others risked still more; and in the fall of 1902 two venturesome young prospectors, Stimler and Marsh, discovered gold on Columbia mountain and located the Sandstorm and Kendall mines. This section was at first called Grandpa district, but a few months later was renamed Goldfield. One of the accompanying engravings is from a photograph of Columbia mountain, a noted landmark in the Goldfield region. In the foreground is seen the local "brick yard," where numerous "adobe" bricks are drying in the sun. In the rear, and near the foot of the mountain, is the new town of Columbia, also called North Goldfield. Now it consists of a double row of irregularly distributed frame "shacks" and tents and tent houses, but if the mine development meets the anticipations of the miners, it is not too much to expect solid rows of substantial buildings, and the busy scenes of industry, which have so often been seen in the history of the West. One of the views on the front page is that of Goldfield, beyond which is Columbia.

The topography of the southern Nevada desert is well illustrated in this picture. The broad, nearly level valleys, and the low, rolling ridges or abrupt steep mountain slopes, are often without a vestige of vegetation from base to summit, while a tree is unknown in this wilderness in which the miners have built cities in a day. Another view on the front page is that of Tonopah as it appears to-day. These illustrations are from "Greater Nevada," a book recently issued by the Nevada Chamber of Commerce of Reno. Before Butler's fortuitous discovery, Tonopah was a waste of coarse sand and jagged rocks, among which grew the scattering clumps of gray sagebrush, with patches of sand between. A more uninviting land can scarcely be imagined, but even this land has its usefulness and value, as is now abundantly proven in the development of rich mines of gold and silver in this desert region. The sagebrush is seen everywhere in Nevada—and by some it is known as the Sagebrush State.

In the early days of the Comstock some one, who had an extravagant idea of the eternal fitness of

things, conceived the notion that the sagebrush, which grew so abundantly, must have some usefulness and that its mission must in some manner be connected with the vast mineral wealth of the State—that it could not be that its presence was merely a coincidence. This visionary person invented the "sagebrush tea" process for treating the ores of the Comstock, but, for some reason, he failed to make the process work successfully.

One of the first mines developed in the Goldfield district was the Sandstorm. Nothing, perhaps, better illustrates the disadvantages of opening a

in detail. One of the accompanying illustrations is that of the January mine.

The Goldfield district is divided into several separate camps—Goldfield, Columbia and Diamondfield being the principal ones, though no one can tell how soon others may be added. The ores of this district are wholly unlike those of the Tonopah district. In the latter the ores, for most part, are firm and siliceous and present an appearance not unlike fine granular quartz ores elsewhere, but at Goldfield the ore is dense and flint-like, or soft and earthy, much of the latter resembling yellow silt (in which no gold

mine in the desert than the engraving of this now noted mine, on the front page. The rugged, sharp rocks project from the low ridge upon which the mine is situated. Here and there is seen the grotesque yucca, the nearest approach to a tree to be found in days of travel in this region. The "blacksmith shop" occupies the foreground, and is a primitive affair—the two upright posts, with a cap on top, a bellows, and a pile of stones for a forge. The Sandstorm mine has passed this stage since the picture was taken and now has a better equipment. Other noted mines in the district are the January, Combination, Jumbo, Quartzite and Butte. Besides these are many others which it is needless to describe

is seen without a fine glass), and yet some of this extraordinary ore has contained more than \$100,000 in metallic gold per ton, while ore containing \$2000 to \$5000 per ton has not been uncommon in that camp. Hundreds of thousands of dollars worth have been shipped away in sacks, and some of the richest in boxes and sealed tin cans. Most of the mines are worked by the leasing system, and many of the richest deposits have been found by leasers lying exposed on the surface, or only a few feet beneath it, covered by sand or loose rocks and debris. Often shafts are sunk at random, and in some instances these ventures have been well rewarded by fortunate discoveries of pay ore, and pay rock in Goldfield district means ore

\* See illustrations on front page.

which will not go much below \$100 per ton—for transportation charges and other expenses incidental to ore shipment under the existing circumstances make high-grade ore a prerequisite to success and profit. These conditions will undoubtedly be improved this year, as mills are already being built in the district and much of the ore now considered low grade will be worked in them at a handsome profit.

Croppings on the Archer Group, 2 Miles S. E. of Tonopah, Nev.

One company in Goldfield district, the Sierra Nevada Development Co., which is also operating near Tonopah, is about to undertake a method of prospecting at Goldfield not yet tried in this region—that of sinking bore holes in what appear to be favorable places. This company has been sinking shafts and running crosscuts on several of their claims, near the Sandstorm, and on the Silver Pick, adjoining the January lease, they have a 110-foot shaft and will put in a steam hoist. Red Butte No. 1 lease is also being developed by them and, although J. D. Hoff of San Francisco, Cal., who is the manager,

## Calcium Sulphate in Portland Cement.

Written by R. K. MEADE and W. P. GANO.

If Portland cement clinker is ground just as it comes from the coolers, without the addition of any retarding substance, says the Chemical Engineer, the resulting cement is entirely too quick setting to allow

of its being properly worked. It is therefore the general practice to either grind a small percentage, usually 2% to 3%, of gypsum with the clinker or else to add to the cement just before it is shipped, a corresponding percentage of finely ground plaster of paris in order to regulate the set so as to give time for working, tamping and troweling. At some mills coarsely ground plaster of paris, or calcined plaster as the manufacturers call it, is added to the clinker before grinding.

Le Chatelier made many experiments on the effect of the addition of gypsum and plaster of paris to

The January Lease, Goldfield, Nev.

reports that good values have been opened up, on these claims no shipping ore has yet been found. Believing that prospecting can be more expeditiously and less expensively carried on by drilling holes systematically, this idea is now being put into execution by Mr. Hoff and, if successful, will no doubt do much to simplify the method of prospecting heretofore followed in these desert regions. The prospecting drill has been employed more or less extensively in testing gold-bearing gravel, but its application to the prospecting of quartz veins is somewhat of an innovation.

## Test of Air Lift Pumping Plant.

The Ingersoll-Sergeant Drill Co. reports the following results secured in a test made recently on a Pohle air lift pumping system installed in a southern brewery. The compressor furnishing air was an Ingersoll-Sergeant Class E machine, size 10x10 inches, and it was run at a speed of 100 revolutions per minute, corresponding to a piston displacement of 89 cubic feet of free air per minute. In this test the air and water pipes were lowered to a depth of 167 feet below the surface to clean out 33 feet of sand and dirt at the bottom of the casing, necessitating deep submergence, and accounts for the unusual air pressure required at the compressor. After the well is cleaned out, the pipes will be raised until a depth of 98 feet is reached, when an air pressure of forty or forty-five pounds will deliver the required quantity of water. The details of the test are as follows: Original depth of the well, 223 feet; depth of the well when the test was made, 183 feet; diameter of the well casing, 7½ inches; standing water level, 14 feet; drop in level when pumping, 21 feet; lift above the surface, 81 feet; total lift from lowest water level, when pumping, to the point of discharge, 44 feet; depth through which water and air pipes were lowered, 167 feet; submergence, 74%; quantity of water lifted, 264 gallons per minute; air pressure at starting, 68 pounds; working air pressure, 60 pounds; diameter of water discharge pipe, 3½ inches; diameter of air pipe, 1½ inch; horizontal distance from receiver to well, 246 feet.

NEVER has prospecting in the desert regions of California, Nevada and Utah been so active as now. This is due partly to the recent development of rich mines in Tonopah and Goldfield, and partly to the construction of the new railroad, much of the prospecting done in anticipation of cheaper transportation.

2H<sub>2</sub>O, containing 43.91% SO<sub>3</sub>.

The results are given in the tables below.

The first column shows the percentage of gypsum, etc., added to the cement. By percentage is not meant the percentage of gypsum in the mixture, but the percentage of the weight of cement in gypsum which is added. For instance, 2% means 2 grams of gypsum added to 100 grams of cement.

TABLE I.

Showing the Effect of Plaster of Paris on Setting Time of Cement.					
Percentage of Plaster of Paris Added.	Percentage of Water Used to Make Pats.	Initial Set.		Final Set.	
		Hours.	Minutes.	Hours.	Minutes.

20	23	2	20	5	0

TABLE IV.

Showing Effect of "Set" Plaster of Paris on Setting Time of Cement.

Percentage of "Set" Plaster of Paris Added.	Percentage of Water Used to Make Pats.	Initial Set.		Final Set.	
		Hours.	Minutes.	Hours.	Minutes.
1	23	0	8	0	40
2	23	1	45	5	0
3	23	2	0	5	20
4	23	1	45	6	0
5	23	1	55	5	35
6	23	2	15	5	50

The second column shows the percentage of water used for the pat, being the amount necessary to obtain a mortar of normal consistency as determined by the ball test. The third column shows the "initial set" or the time necessary for the cement to harden sufficiently to bear the light Gilmore wire ⅛ inch in diameter loaded with one-quarter pound. The fourth column shows the "final set" or the time necessary for the cement to harden sufficiently to bear heavy Gilmore wire ½ inch in diameter loaded with one pound.

While it is probable that a repetition of these tests upon other samples of cement would show quite a variation from the above figures, still the general facts given below will show in all of them, as we have found by checking the above on many samples of quick setting and unplastered cement.

Referring to the tables, it will be seen that there is little choice in the four forms of calcium sulphate so far as efficiency goes, all doing the work of retarding the set about equally well. This is to be expected. If the retardation is due to chemical action, there is no reason why any one of the forms should not be as efficient as the others because they all have approximately the same solubility, that of 1 part in 400 to 500 parts of cold water. The solution of any of the four would merely be one of a mixture of two kinds of ions, CaO, and SO<sub>3</sub>, and the SO<sub>3</sub> anions would be as free to react on the aluminates of lime if their source was gypsum as they would if they came from plaster of paris.

It will be noticed, by reference to Table I, that 2% plaster of paris produced the maximum retardation of the set. Larger quantities than this had the effect of quickening the set of the cement. This maximum, of course, varies with different cement, but with all it will be found that there is a point beyond which additions of plaster will be attended with shortening instead of further lengthening the setting time of the cement. The phenomena is, no doubt, due to the fact that plaster of paris itself is very quick setting. This explanation is strengthened by the fact that the addition of large quantities of calcium sulphate in the other three forms (see Tables II, III and IV), none of which have any setting properties of their own, does not cause any quickening of the set.

In view of the fact that both gypsum and set plaster of paris, which is merely plaster of paris reverted into gypsum, will slow the set of cement, there can be nothing in the theory that plaster loses its control, in time, over the cement, for the only change which the plaster can undergo is to absorb water from the air forming gypsum. We must, therefore, seek for another solution of the matter. Clifford Richardson suggested one in his paper on the "Constitution of Portland Cement," read before the Association of Cement Manufacturers at Atlanta City last June. His theory is that the tension in the solid solution of calcium silicates and aluminates which constitute cement, is released by changes in temperature, etc.,

Portland cement. He concluded that the governing action which it exercised over the cement was due to the formation of certain soluble compounds between the sulphuric acid of the calcium sulphates and the very active calcium aluminate of the cement which caused quick setting. He also stated that either gypsum or plaster of paris could be added to slow the set and that the addition could be made either before or after burning. Since, however, calcium sulphate is decomposed at temperatures decidedly below that at which Portland cement is burned there would be a decided disadvantage, owing to loss of SO<sub>3</sub>, in adding gypsum before burning. Indeed, from experiments made by one of the writers, if all the sulphur entering the kiln came out with the clinker as calcium sulphate there would be no need to add gypsum or plaster of paris.

In spite of Le Chatelier's experiments, it has been the theory generally held in this country that gypsum would not retard the set of cement, but that the only form of sulphate of lime which would do this is plaster of paris; that where gypsum is ground in with the clinker, this is transformed into plaster of paris, the heat generated during grinding being sufficient to drive off the water and makes the change from CaSO<sub>4</sub> · 2H<sub>2</sub>O to (CaSO<sub>4</sub>)<sub>2</sub> · H<sub>2</sub>O. It is true that in many cases the heat generated by the friction of the grinding machinery is sufficient to drive off the water, as the writer has frequently tested cement fresh from the tube mill and found it over 130° C, the temperature at which gypsum loses three-quarters of its water of crystallization. Indeed Shenstone and Cundall state that gypsum begins to lose its water of crystallization at 70° C in dry air.

The reason is also commonly given for the quickening of the set of some cements when fresh were of normal set, but which on storage had become quick setting, that the change was due to the reversion of the plaster of paris (CaSO<sub>4</sub>)<sub>2</sub> · H<sub>2</sub>O to gypsum or CaSO<sub>4</sub> · 2H<sub>2</sub>O. To test these various contrary theories and statements the writers carried out the following experiment:

A sample of cement was prepared by grinding fresh normal clinker in the usual way without the addition of any retarder. To separate portions of this were added in different percentages, finely ground:

1. Plaster of paris (CaSO<sub>4</sub>)<sub>2</sub> · H<sub>2</sub>O, containing 53.18% SO<sub>3</sub>.
2. Gypsum CaSO<sub>4</sub> · 2H<sub>2</sub>O, containing 44.32% SO<sub>3</sub>.
3. Dead burned gypsum CaSO<sub>4</sub>, containing 55.21% SO<sub>3</sub>.
4. Set plaster of paris, dried in open air CaSO<sub>4</sub>,

setting free some aluminate which makes the cement quick setting again.

It may be interesting to note that all of the above pats stood the boiling test, yet one of the newest books on cements (Falk "Cements, Mortars and Concretes") states that large percentages of plaster of paris cause cement to blow and expand.

We are aware that the above statements on the retarding of the setting time of Portland cement by gypsum will upset some of the theories of those who add plaster of paris to cement just before it is shipped. If it is properly mixed with the cements there are certainly points in favor of adding the sulphate here. We do not see, however, why finely ground gypsum would not do the work just as well, saving the cost of calcining. On the other hand, if the gypsum is added to the clinker, it is sure to be finely ground and thoroughly disseminated throughout the cement, two things necessary with any form of sulphate if it is to act as a retarder. There will be no danger of the gypsum failing to do its work, whether the temperature is low or high during grinding, and if the cement becomes quick setting on storage the blame cannot be laid to the gypsum. It must be remembered, however, that plaster of paris contains more sulphuric acid than gypsum, 290 parts of the former being equivalent to 344 for the latter, or a ratio of 87:100, so that plaster of paris, weight for weight, is the more effective of the two. Along this line dead burned gypsum is still more effective and should be cheaper than plaster calcined by the kettle process.

### Methods and Costs of Blasting and Handling Boulders.

One of the most important items of cost in hydraulic and placer mining generally, as well as in quartz mining, is that of handling boulders and the large rocks resulting from blasting. This is treated at some length in an article in the Engineering News, by D. J. Hauer, from which the following is abstracted:

The methods of handling boulders after they are broken up are by (1) steam shovels, (2) derricks, (3) cable ways, (4) sleds or lizards, (5) carts or cars, and (6) by wagons. \* \* \* Ordinary hand power, horse power and steam derricks can be used to advantage in hauling boulders, and in some classes of work money is frequently lost by contractors not providing themselves with the proper derricks. In borrow pits, on sidehill cuts on railroads and similar places, there is a ready use for different style derricks. No rule can be set down for styles and uses of derricks, but the conditions surrounding the work in hand must govern the selection of the derricks. To handle stone successfully with derricks, it is necessary to have several chains, sets of grabs and stone boats.

When only a few large boulders have to be handled from time to time, and loaded into a small dump car or wagon, a three-legged derrick and a triplex block can be used very economically. The derrick can be set up quickly over the boulder, and with the block the stone can be picked up and the car or wagon run under the suspended boulder and the load let down. This will be found less expensive than breaking the boulder up so it can be loaded by hand.

When a steam derrick has to be frequently moved short distances, it will be found expedient to mount both engine and derrick on a low, broad gage (10 feet) car, and move the car from place to place on a track, which can be built of wood. Uses for a car of this description can be found in both railroad and canal construction, and boulders weighing five tons can be handled.

In handling boulders with derricks, mud capping to break up boulders should never be resorted to, as there will always be time to do the necessary drilling to block the rock. At times the charge may be placed under the stone, but owing to the great chance of injuring the derrick by flying pieces of rock, this method of boulder breaking cannot be recommended under such circumstances. One mode of breaking up boulders when derricks are used is to raise up a heavy iron weight, and by tripping it, drop it on the stone to be broken. The weight is generally a ton. The writer has seen this method used to break metal around blast furnaces and stone in quarries, and as it is a money-saving device, its use could be much extended.

The most important feature in handling the boulders is the breaking of the larger masses into sizes which can be readily handled by the mechanical devices at hand.

**BREAKING UP BOULDERS.**—We now come to consider the different methods of breaking up boulders and the relative merits and costs of each. The following six methods can be used: (1) Boulders can be broken with plug and feathers, (2) by heating and pouring water on them, (3) by sledging, (4) by mud capping, (5) by blocking, and (6) by placing a charge of explosives under the boulders. Each of these modes has its uses and misuses, and it is hoped to point out a few of these, and give some cost data.

**PLUG AND FEATHERS.**—(1) Drilling the rock with a hand drill and then splitting with plugs and feathers is of great use, when the stone is to be used for building purposes, as for culverts and bridges. The cost of this work varies with the hardness of the

rock, the size to which the stone is to be broken and the price paid for such work. Good hand drillers are paid \$1.50 to \$3.50 per day, according to the locality. In the South negro hand drillers are paid \$1.50, while in some sections union stone cutters do this work for which union wages are paid. In soft sandstone a good hand driller can drill a hole 3 inches deep in 3 minutes, while in the harder sandstone and gneiss from 5 to 7 minutes will be necessary, and in the hardest granite 10 minutes may be consumed. These conditions make it difficult to give any idea of cost of breaking boulders by this method. When an air compressor is at hand this work can be cheapened by the use of pneumatic drills.

**THE HEATING OF BOULDERS.**—(2) The heating of boulders to facilitate their breaking has only a limited use from an economical and practical standpoint. No one would wish to use it in a railroad cut and similar places, but there are times when it becomes both a time and money saver. In clearing a piece of timber and to grade streets through it, the land was covered with surface boulders of trap rock. It was necessary to burn the brush and top wood. Accordingly, the wood was piled in heaps around the boulders, and when the rocks were still hot, water was thrown over them, causing them to crack and break, necessitating but little work with a sledge and none with explosives. In this instance, as the wood had to be burned, the only cost was the putting on of water—certainly a great saving in money. This method can be recommended for similar uses, and especially for surface boulders of 4 cubic yards or less. Large boulders cannot be heated enough. Anyone trying this method for the first time should be warned against small pieces of rock popping off when the water is poured on. This was found to happen now and then with trap rock.

The boulder must be heated thoroughly before pouring the water upon it, to insure breaking, for when only partly heated the surface only spalls off.

**SLEDGING.**—(3) Under a competent and watchful foreman many large-size boulders can be broken up with a stout sledge and gad, saving the use of explosives. A common laborer, as a rule, knows nothing of the rift of a stone and cares but little to learn. He usually begins hammering upon the face that the stone presents to the position that he happens to occupy, and unless the foreman interferes, he will waste time. Upon one occasion the writer watched a man use up 10 minutes in this manner, and after the foreman and man were shown where to direct the blows, the rock was broken up so it could be conveniently handled in less than 2 minutes. Frequently the use of the sledge prevents other men from working, and at times men will stop to watch the operation (there seems to be something fascinating about it) unless the foreman is ever watchful. For these reasons sledging of boulders should be planned out carefully and it should be the constant endeavor to have it done when the use of the hammer will not interfere with other men.

By looking closely for seams and cracks and taking advantage of these, and at other times using the pean end of the hammer with the rift of the rock, many boulders containing 1 cubic yard or less can be quickly broken. At times to turn the stone and keep an air space beneath the rock will mean a great advantage in breaking the boulder. Unless the foreman is alert, the men will in most cases break up the stone too small, and will also use the pean end of the hammer, when the stone should be hit with the full face.

A gad will be found useful in connection with a sledge, as stones can at times be split cheaply with the help of gads, when it would take considerable time to make an impression upon them with only a hammer. It is necessary to have several different size gads and some water will be useful to wet the spot upon the stone where the gad is to be started. If good judgment is exercised in directing men in the use of sledge and gad, money can be saved in breaking up boulders with this method over all others. The following are some records of cost of breaking up boulders by sledging: (These figures do not include moving the pieces after the boulder is broken, but all the pieces could be easily banded. Wages paid were \$1.50 for a working day of 10 hours.)

1. Hard blue sandstone,  $7\frac{1}{2}$  cubic feet, 1 man 3 minutes makes a cost of  $\frac{1}{4}$  cent or 2.7 cents per cubic yard.

2. Blue sandstone,  $12\frac{1}{2}$  cubic feet, 1 man 5 minutes, 2 men 2 minutes, makes a cost of 21 cents or 4.86 cents per cubic yard.

3. Blue sandstone, 16 cubic feet, 1 man 3 minutes makes a cost of  $\frac{1}{4}$  cent or 1.25 cents per cubic yard.

4. Red sandstone (not so hard), 1 cubic yard, 3 men 10 minutes makes a cost of  $7\frac{1}{2}$  cents per cubic yard.

5. Blue sandstone, 12 cubic feet, 2 men 8 minutes makes a cost of 4 cents or 9 cents per cubic yard.

6. Red sandstone, 23 cubic feet, 3 men 5 minutes makes a cost of  $3\frac{3}{4}$  cents or 4.1 cents per cubic yard.

7. Red sandstone, 18 cubic feet, 1 man 4 minutes makes a cost of 1 cent or  $1\frac{1}{2}$  cents per cubic yard.

**MUD CAPPING.**—(4) Mud capping a boulder consists in placing a charge of dynamite, with a cap and piece of fuse inserted into the charge, upon the top of a boulder, and after covering the charge well with mud, exploding it. By the uniform force exerted by dynamite in all directions, the boulder is generally

broken up so that the pieces can be loaded and carried away. This work can, as a rule, be done so quickly that the method has come into universal favor among foremen, but the great objection to it is the almost prohibitory cost. On account of this great loss mud capping should be condemned, as upon most occasions cheaper methods can be used. The only reason that should ever commend it to the thoughtful contractor is the saving of time in preparing the shot. For this reason, in thorough cuts, mud capping may occasionally be resorted to, but in sidehill cuts and borrow pits, where the work of sledging and drilling will not interfere with the labor of the muckers, this method should under no circumstances be used. In solid rock excavations, especially in sidehill cuts, after the cut is once shot, the amount of explosives necessary to break up the material should be very small, as methods 3, 5 and 6 can be used almost exclusively, but any contractor who keeps an accurate account of explosives used at different places will find that frequently, owing to the fact that foremen will mud cap almost every boulder, the cost of breaking up boulders will oftentimes exceed the original cost of loosening the material.

To illustrate this point the following figures are given: In a large tunnel approach a shot was made with thirty-six kegs of powder, the entire cost of explosives used for this blast being \$50.91. From this shot 1054 cubic yards of solid rock and 512 cubic yards of loose rock were excavated, and the cost of explosives used to break up the boulders so they could be handled was \$90.54, there being over 750 pounds of 40% dynamite consumed. The foreman in charge of this cut was considered a capable man, and each month showed a profit on his work. He nearly always mud capped his boulders, and as shown above, he certainly used too much dynamite. He could have made a large profit by using better judgment in breaking boulders. In this example no blocking was necessary to trim up the sides or bottom of the cut, as the work was being done in two lifts and this shot was made on the upper lift.

1. Upon another occasion, after a heavy blast was made in a thorough cut, a large sandstone boulder measuring 17 cubic yards was thrown upon some loose material across the cut, preventing the crew of ten men from working until it was broken up. To block it, two holes would have been necessary, and on account of the loose material under the rock it was not advisable to put the charge there. Accordingly, at a cost in labor of 30 cents, and 21 pounds of dynamite at 13 cents per pound and two electrical fuses costing 9 cents—making a total cost of explosives of \$2.82—the stone was broken up successfully and the work went on. This was accomplished at a cost of 18.6 cents per cubic yard, and may be considered as one of the few cases where this method can be recommended.

The following are some additional records of costs of mud capping. Labor was paid \$1.50 per day of 10 hours, 40% dynamite cost 10 cents per pound, caps 60 cents per hundred and fuse 42 cents per hundred feet:

2. Red sandstone, 1.6 cubic yard, labor 8 cents, dynamite 20 cents, cap and fuse 2 cents—total cost 30 cents, or nearly 18 cents per cubic yard.

3. Red sandstone, 1 cubic yard, labor 8 cents, dynamite 15 cents, cap and fuse 10 cents—total cost 25 cents.

4. Two red sandstone boulders same size,  $\frac{1}{4}$  cubic yard, and same cost as follows: Labor 8 cents, dynamite 10 cents, cap and fuse 2 cents—total cost 20 cents or  $26\frac{2}{3}$  cents per cubic yard.

5. Hard blue sandstone, 1 cubic yard, round boulder, labor 8 cents, dynamite 15 cents, cap and fuse 2 cents—total cost 25 cents. This blast did not even crack the boulder and it was shot a second time, labor being 11 cents, dynamite 10 cents and cap and fuse 2 cents—making a total cost per cubic yard for the two blasts of 48 cents. The second shot cracked the boulder, and it was still necessary to use a sledge and gad on it, at a cost of 3 cents. Total cost 51 cents.

6. Blue sandstone, 1.2 cubic yard, labor 8 cents, dynamite 20 cents, cap and fuse 2 cents—total cost 30 cents, or 25 cents per cubic yard. This broke the boulder, but a part of it had to be sledged at a cost of 5 cents.

**BLOCKING.**—(5) The blocking of boulders is a much cheaper way of breaking them up than mud capping. It should always be used in preference to that method, except when too much time will be consumed by a crew of men waiting for the drilling to be done, as shown in example of cost No. 1 (as given under mud capping). Under such circumstances the time consumed would be a greater cost to the contractor than the extra amount of dynamite. Then, too, on large, thin boulders, to drill one hole would result only in breaking the stone into such pieces as would again have to be broken—and the many holes might equal the cost of extra dynamite. Under such circumstances if this method (6) cannot be used, mud capping will have to be resorted to, to do the work economically.

A hole properly charged and covered with mud will effect a saving of 60% to 70% of dynamite, over mud capping. The bottom of cuts should always be blocked, as this sort of work can always be planned ahead, and it is the only way a shallow rock bottom

can be taken up accurately and at a minimum cost. Of course machine drills on this class of work will save money over hammers and drills. Surface boulders, where it is not possible to use method (6), should always be blocked. Occasionally on very large surface boulders black powder can be used, but as a rule dynamite will be given the preference unless it is desired to use the stone for building purposes, when engineers will forbid the use of dynamite. This has ever been done in some cases where the stone is to be used for concrete.

In the following examples of costs the prices were the same as those named under mud capping:

1. Red sandstone boulder, 13 cubic yards, broken up entirely.

Drilling 3-foot hole, at 25 cents per foot	.....	\$ 1 05
Dynamite	.....	0 20
Cap and fuse	.....	0 02
Labor	.....	0 18
Total	.....	\$ 1 45
Cost, per cubic yard, 11.1 cents.		

2. Blue sandstone, 3 cubic yards, broken up entirely.

Drilling, 1-foot hole	.....	\$ 0 40
Dynamite	.....	0 10
Cap and fuse	.....	0 02
Labor	.....	0 08
Total	.....	\$ 0 60
Cost, per cubic yard, 20 cents.		

3. Red sandstone, 4½ cubic yards, broken up entirely.

Drilling, 1½ foot	.....	\$ 0 52
Dynamite	.....	0 12
Cap and fuse	.....	0 02
Labor	.....	0 10
Total	.....	\$ 0 76
Cost, per cubic yard, 16.9 cents.		

4. Blue sandstone, 2½ cubic yards, entirely broken up.

Drilling 1-foot hole	.....	\$ 0 30
Dynamite	.....	0 05
Cap and fuse	.....	0 02
Labor	.....	0 05
Total	.....	\$ 0 45
Cost, per cubic yard, 18 cents.		

5. Blue sandstone, 2 cubic yards, entirely broken up.

Drilling, 7-inch hole	.....	\$ 0 20
Dynamite	.....	0 10
Cap and fuse	.....	0 02
Labor	.....	0 04
Total	.....	\$ 0 36
Cost, per cubic yard, 18 cents.		

In all these cases boulders were broken up so that they could be loaded by hand. The item of labor is the time consumed by the crew of men in putting mud on the charge and leaving and returning to the cut. In case No. 1 this item is large, as that boulder was broken alone, but in the other cases a number were broken at one time. In case No. 3 but one other boulder was broken with it, so again this item is comparatively high.

**PLACING CHARGE UNDER BOULDER.**—(6) The method of placing the charge of dynamite under the boulder in order to break it has not been used extensively, and for this reason it is difficult to obtain costs of this method. That it can and should be used on account of its cheapness over other methods should commend it to contractors. The charge can easily be placed under the rock by either raising the boulder up with bars or levers, or churning a hole under it with a drill. In some cases the boulder can be turned over and the charge placed, as this is being done. At least 50% to 60% of the charge necessary to mud cap a boulder can be saved by this method and the work can be done as quickly. The rock, as a rule, will not only be broken up, but most of it will be thrown out of the cut. For this reason where there can be no waste of material, engineers may prohibit this method. Of course where the material that the boulder is lying on is soft, this method cannot be used successfully. Its greatest use will be found on hard rock bottoms, also in breaking up and moving surface boulders.

The following examples of costs are given for boulders broken off in this way.

1. A surface boulder, containing 50 cubic yards, was moved off the right of way at the following cost:

Four kegs of powder, at \$1.64	.....	\$ 6 56
Cap and fuse	.....	0 04
Dynamite, 2½ pounds, at 16 cents per pound	.....	0 40
Labor	.....	5 50
Total	.....	\$12 50
Cost, per cubic yard, 15 cents.		

The labor consisted of one foreman one day at \$3, two men at \$1 a day each and one boy a day at 50 cents. The entire boulder was moved a distance of at least 40 feet. The labor item was large, as it was necessary to carry a large amount of sand to be used in tamping the load well under the boulder.

2. A red sandstone boulder, 9 cubic yards, was completely blown away at the following cost: Labor 10 cents, dynamite 5½ cents, cap and fuse 2 cents—total cost 17½ cents; cost per cubic yard 1.94 cents. Labor in this case was \$1.35 per day and dynamite cost 11 cents per pound.

3. A large boulder sticking into the base of the slope of a cut had 1½ cubic yards shot off it by putting the charge under the projecting end. Labor 13 cents, dynamite 16½ cents, cap and fuse 2 cents—total cost 31½ cents; cost per cubic yard 21 cents.

About cubic yard was thrown out of the cut and the rest was broken up, so it could be handled.

Labor and dynamite cost the same as in case No. 2. The next case was blue sandstone and the boulders were entirely blown away. Labor was paid \$1.50 and dynamite cost 10 cents per pound.

4. Boulder, 1½ cubic yards, labor 9 cents, dynamite 8 cents, cap and fuse 2 cents—total cost 19 cents; cost per cubic yard 15.2 cents.

## Early Mining Laws and Locations.

Written for the MINING AND SCIENTIFIC PRESS.

The United States mining law is to a great extent based upon the early customs, rules and regulations of the miners of pioneer days. In the early days of California and Nevada there were few laws to guide the miner, and he from necessity created a code of laws, simple in themselves, but which were considered sufficient for the time being. As early as 1851 the California State Legislature passed a law which recognized the rules and regulations of the miners and declared that they might legally be offered as evidence in the controversies which might arise over the possession of mining claims or their operation, and that "these rules and regulations should govern the decision of the action when not in conflict with the constitution or laws of the State or of the United States." When in 1859 the Comstock was discovered the miners of Washoe followed the example of the California miners, and accordingly framed a code of regulations for their own government. The first code of mining laws adopted in Nevada was in part as follows:

**ARTICLE I.** There shall be elected one justice of the peace, one constable and one recorder of this district for the term of six months.

**ARTICLE IV.** The duty of the recorder shall be to keep in a well-bound book a record of all claims which may be presented for record, with the names of the parties locating or purchasing, the number of feet, where situated, and the date of location or purchase; also to return a certificate for such claim or claims.

**SECTION 7.** Evidence of record of claims shall be considered title in preference to claims that are not recorded; nor shall the recorder record more than one hill, dry gulch, or ravine claim in the name of an individual unless the same has been purchased.

**Sec. 8.** All claims shall be properly defined by a stake at each end of the claim, with the number of members forming said company and the number of feet owned.

**Sec. 9.** All claims shall be worked or the notice renewed in sixty days from the date of record, and no claim shall exceed 200 feet square, hill claims excepted, which may be reduced to 50 feet front.

**Sec. 10.** The recorder shall be allowed the sum of 25 cents for recording the claim of each individual, or member of a company.

**Sec. 11.** No Chinaman shall be allowed to hold a claim in this district.

**Sec. 12.** This district shall include all the territory from the meridian of Johnstown to Steamboat valley.

**Sec. 13.** All quartz claims shall not exceed 300 feet in length, including the depths and spurs.

**Sec. 14.** Any person discovering a quartz vein shall be entitled to an extra claim on all veins he or they may discover.

**Sec. 15.** All persons holding quartz claims shall actually work to the amount of \$15 to the share within ninety days from the time of locating.

**Sec. 16.** All persons holding quartz claims and complying with Section 15 shall hold the same for term of eighteen months as actual property.

**Sec. 17.** All quartz claims shall be duly recorded within thirty days from the time of locating.

**Sec. 18.** No person shall locate more than one claim or a vein discovered.

**Sec. 19.** Any and all persons locating for mining purposes shall have the same duly located within ten days from the time of locating.

**Sec. 20.** Resolved, That the above rules and regulations shall be signed by citizens of this district (Gold Hill), and all who may locate hereafter.

These "rules and regulations" are from the early records of the Gold Hill mining district. It is scarcely necessary to call attention to the conflicting provisions of several of the regulations and the uncertainty of the meaning of others. It is evident that such a code of laws could only result in conflict in a camp of rich mines, but these and similar rules and regulations in Nevada and California were the basis of the present mining law of the United States, and to a less extent of the several States also.

In the early days prospectors appeared to have a very crude idea of these laws, doubtless due to the fact that the laws were themselves crude. Even to-day prospectors write strange legends upon their location stakes. Some of the notices posted on early Comstock claims are among the most interesting of their kind, and readily explain why almost interminable litigation resulted in that district. Here are a few specimens of the remarkable conception of the early Comstocker of the mining rules as promulgated by the Gold Hill mining district:

### NOTICE.

That we the undersigned claim 600 feet of this quartz vein, commencing at the south end of James Cory claim and running south 600 feet and two claims.

LEE JAMES,  
JNO. MURPHY.

Another notice in the vicinity of this contained the following:

### NOTICE.

That I the undersigned claim—claim one claim on this quartz vein of 300 feet, commencing with the south end of Lee James & Co, and running south 300 feet to the line and one claim.

J. D. WINTERS.

Still another and more peculiar notice was the following:

### NOTICE.

That we the undersigned do claim 100 feet wide running up the hill 400 feet including quartz and surface from notice near a cedar stump. May 15, 1859. This claim lies south of Penrod and Comstock claim, Six-Mile canyon.

A. WHITE,  
JOS. CURBY,  
A. G. HANACK.

The next notice was on the ground near the last mentioned, and read as follows:

### NOTICE.

That we, the undersigned, do claim 500 feet, commencing at J. B. Winters' claim Running south including surface and quartz with all of it dippings, and angles, spurs.

F. B. ABERNATHIE,  
P. M. BALDWIN,  
E. BELCHER,  
R. D. SIDES.

These notices are of the greater interest from the fact that they cover a good portion of what afterward became the most renowned mine in the world—the Consolidated California & Virginia mine.

From the above it is clearly evident that the elements which now form the principal source of contention in mining litigation entered early into the history of mining in the West, and "dips, spurs and angles" were recognized from the beginning as forming in some indefinite way a portion of a vein system, and that the privilege of following them should be reserved to the locator, as well as the main vein which was the subject of location.

Although more than fifty years have passed since these early days, and the mining laws have become more or less familiar to all engaged in mining, prospectors still persist in making defective locations, referring their corners to objects not permanent, and exercising little care to see that there is no conflict with pre-existing rights. Oftener they fail to erect proper posts or monuments at the corners, or if they fail do not take the trouble to renew them. It is rarely that there is trouble or litigation over a valueless mine, but in the event of a valuable property being developed it is almost impossible to avoid a lawsuit if every detail of the requirements of the mining laws is not strictly complied with, and even when they are it is sometimes difficult to retain possession of a very valuable property without an expensive suit to establish rights gained by this faithful observance of the law. Often prospectors do not understand the law in reference to location of claims, and do strange and unnecessary things. One a few months ago read a description in a book "how to locate a mining claim," illustrated by a diagram. In locating a claim he gave the claim the name taken for the purpose of illustration in the book, and then at the point of discovery posted a notice bearing another name—the name he desired to give the location. He had both notices recorded in the office of the county recorder. This is merely a single instance of many wherein it is clearly evident the average prospector either does not understand the law, or is careless in following it. Some are intentionally so, believing that this laxity affords them an opportunity to amend the location later so as to gain some advantage when in possession of more definite knowledge as to the strike, dip, etc., of the vein, but an amended location cannot be made which will encroach upon the rights of others who have located since the original claim was taken up. If the outcrop dip and other physical features of the vein are obscure this is the misfortune of the locator, who must do the best he can under the circumstances, and if there is any excitement over locations in his vicinity, for self-protection he must do it quickly or he will lose his opportunity.

## THE PROSPECTOR.

The specimens from Holmes, Wyo., have been determined as follows: No. 1, principally lead carbonate in quartz, also a small amount of wulfenite (lead molybdate); there is also a small amount of copper present; the green spots are copper carbonate. No. 2 is granite, largely consisting of pink feldspar; the metallic scales on the granite are specular iron (hematite). No. 3 is a much altered granite, but different from No. 2; rocks containing as much iron oxide as No. 3 are sometimes gold bearing.

The rocks from Cave Creek, Ariz., are identified as follows: No. 1. Quartz in which is a little chalcocite (copper glance). The green color is due to a stain of copper carbonate. The percentage of copper present is small, but suggests the advisability of prospecting and development in the vicinity of its occurrence. The scattering seams and bunches may overlie a larger body of ore, but this it is impossible to tell, even when on the ground. No. 2 is quartz containing a large amount of epidote, the yellowish-

green mineral. A small amount of garnet is also present. The rock presents the appearance of having been altered from limestone and probably occurs near the contact of an eruptive mass. No. 3 is similar to No. 2, but contains more quartz and less epidote. No. 4 is also a much altered rock, difficult to determine, but presents more the appearance of an altered eruptive rock than one of sedimentary origin. In many of the copper mines of southeastern Arizona the surface showing is small, but this cannot always be depended upon, for in some instances a poor showing at the surface does not improve with depth, and again a fairly good showing at the surface grows poorer upon sinking and finally "peters out."

The rocks from Hedley, B. C., are as follows: The dark brown sample with white crystals scattered through it (number illegible) is diabase porphyrite; No. 2 is diorite somewhat altered. It contains considerable sulphide of iron and a little copper; No. 3 is grano-diorite in which is seen glistening iron sulphide; No. 4 is essentially all quartz, though evidently an altered eruptive rock, probably similar originally to No. 2. One sample (number illegible) is quartz in which is seen a large amount of galena (lead sulphide). The other three pieces are apparently diabase. The specimens were all too small and not protected from rubbing upon each other by separate wrappings.

Of the two rock specimens from Callahans, Cal., No. 1 is a granular quartz rock, apparently metamorphic, and occurring in kidneys or lenses in mica schist; occasionally rock of this character is gold-bearing, but the values are always spotted, though sometimes high grade. No. 2 is diorite aphanite, a basic, compact, flint-like intrusive rock breaking with conchoidal fracture; the specimen contains considerable pyrite in minute crystals disseminated through the mass.

The samples from Cerrillos, N. M., are: No. 1, a granite dike rock, containing large phenocrysts of soda-lime feldspar. The reddish color is due to iron oxide. No. 2 is granitic detritus, in a semi-cemented condition. The black material is largely carbon, which loses its color on burning. The white pebbles in this material are not crystals, but water-worn fragments of quartz and feldspar from granite.

The small rock fragments from Temascattepec, Mexico, are lava, in which are crystals of olivine, quartz and calcite. The pieces are too small for determination.

## The Mines of Cripple Creek, Colo.\*

NUMBER IV—CONCLUDED.

Written by W. LINDGREN and F. L. RANSOME.

There is in fact little indication of enrichment in the oxidized zone, such as is so often found in gold-quartz veins of the normal type. Frequently the fresh telluride ore is extremely rich, and high-grade pockets occur impartially in oxidized and fresh portions of the veins. Neither would it be correct to say that there is a gradual decrease in the value of ore in depth. It is quantity, not value, which decreases.

While it is certain that pyrite, and possibly other minerals, has formed at more than one period during the mineralization of the district, and while it is equally clear that in general the rich tellurides were the last of the ore minerals to be deposited, there is apparently no evidence that either one of these minerals has been formed by enriching solutions at the expense of primary minerals. So far as definite conclusion is warranted in an investigation as yet incomplete, it appears that the unoxidized ore deposits of the Cripple Creek district represent the product of one general period of mineralization and that they have not been appreciably modified by secondary enrichment during the subsequent erosion of the region.

**UNDERGROUND WATER.**—The conditions of underground waters are interesting and somewhat unusual. A dry climate and a heavy percentage of run-off minimize the annual additions to the underground supply. Nevertheless, the ground-water level is not unusually deep, and large quantities of water are encountered in all the mines below that level. The original water surface of the district in the volcanic rocks stood at elevations of 9400 to 9700 feet, or 100 to 600 feet below the surface of the ground. At first pumping was commenced at individual mines, but it was soon found that the radius of drainage had unusual length—that is, that one mine would drain others at a distance. Drainage tunnels were then undertaken, and the Chicago & Cripple Creek, the Ophelia, the Standard, and lately the El Paso, tunnels were driven, each of which practically accomplished the drainage of a large part of the district almost down to its own level, thus showing that the ground water is limited in quantity and is more of the nature of a local reservoir than a "subterranean sea."

The plug of volcanic rocks which fills the throat of the old volcano is rudely circular, with a diameter of 3 miles. This mass is extremely porous, and is, moreover, cut in many directions by partly filled fis-

tures and sheeted zones, so that water can circulate within it with comparative freedom in several directions. It retains this character down to the greatest depth yet reached. On the other hand, the surrounding granite is relatively impermeable and is less traversed by open fissures. No doubt it contains ground water down to a depth of 2000 feet or more, but in very much smaller quantity, and the circulation of this water must be extremely slow. This is clearly shown by the fact that the water in the breccia is not drained by Cripple creek and Arequa gulch below the level of the points where they leave the volcanic area. Thus the volcanic plug resembles a water-soaked sponge inserted in a hole cut in an impermeable substance. The drainage of the mines

investigations concerning this subject are not yet concluded. It may be said, however, that a sudden lowering of the barometer seems to be the most important factor. Upon such a fall the gas issues in great volumes, but decreases when the barometer remains steadily low for several days. The gas is often very heavy, filling lower parts of drifts and winzes like water, and cases are reported in which it has actually been bailed from a shaft. Its temperature is somewhat higher than that prevailing in the mine under normal conditions.

It has practically no smell or taste, but small quantities of it easily produce effects of suffocation. Miners working in places where this gas is mixed with the air soon experience various forms of physical

Head Frame and Bins of the Exposition Mining & Leasing Co., Cripple Creek, Colo.

is thereby greatly facilitated, as it is not necessary to extend the tapping tunnels to each mine.

The El Paso tunnel, completed in the winter of 1903-4, has an elevation of 8790 feet at the portal. Within a short time it effectually drained not only the Beacon hill mines but also the Gold hill mines, and its influence extended even to the Last Dollar and the Elkton mines. But the foregoing statement in relation to draining the district must be so modified as to exclude a certain part on the eastern side, comprising the mines about Independence on the east side of Bull hill and those on Battle mountain and in the town of Victor, in which the effect of the El Paso tunnel is slight. The Findley, Hull City, Vindicator and Golden Cycle mines about the town of Independence seem to occupy a separate drainage basin, probably divided from the main area by masses of relatively impermeable rock.

The Portland, Stratton's Independence and the other mines near Victor occupy another drainage basin. Of these the Gold Coin and Stratton's Independence have shafts below the level of the El Paso tunnel, and their pumps have probably drained the surrounding territory to a considerable extent. The influence of the drainage tunnel on the Portland mine is a question upon which opinions differ.

The subject of the drainage of the Cripple Creek mines has been actively studied in late years, and valuable contributions to the subject have been made by V. G. Hills and others, who have shown that the water can be tapped, without prohibitive expense, down to an elevation of 7500 feet, or 1300 feet below the El Paso tunnel. For this depth a tunnel  $3\frac{1}{2}$  miles long would be needed. On account of the great porosity of the rocks it is not probable that the next 1000 feet below the El Paso tunnel level will show any great diminution in the amount of water stored in the rocks.

**SUBTERRANEAN GASES.**—During the earlier years of Cripple Creek no unusual amount of mine gases was observed, but, as the shafts and workings deepened, several properties began to experience much annoyance and even serious interference with work, often in spite of vigorous measures for ventilation. These gases appear to issue chiefly from the breccia, especially where it is of porous and loose texture, but they sometimes flow from partly open vein fissures in such quantity that a light held up to the fissures is immediately extinguished. Thus far the mines on Battle mountain and those of the Golden Cycle, Vindicator and Isabella groups have suffered no inconvenience, but most of the mines west of this line have had more or less trouble with this subtle and insidious enemy. At least one mine has been forced to close down entirely, and several others are often obliged to abandon work for days. Sometimes the amount of gas issuing is small, and ordinary ventilation will carry it away. Again it may issue in large volumes and practically fill the mine for some time. In other mines the gas persistently hangs at certain places, forming barriers which can be passed only with difficulty. The outflow of gas is unquestionably related to barometric fluctuations, though it is usually locally reported to be influenced by the direction of the wind. The

distress, and several fatal accidents have been caused by men entering drifts and winzes filled with it.

The characteristics of the gas seemed to point to carbon dioxide, and it is generally so termed. Preliminary determinations of carbon dioxide by a portable apparatus yielded percentages which seemed far too small in comparison with the effects of the gas examined and led to the belief that some other substance was present. Samples were then collected and analyzed. The analyses showed the gas to be a mixture of nitrogen with about 20% carbon dioxide and a small amount of oxygen.

The occurrence of these exhalations over a large part of the ore-bearing area is of much interest. They certainly increase in quantity with depth and it is to be feared that in some cases they may seriously affect mining operations. The evil has proved very difficult to cope with. Ventilation alone has rarely proved efficient and the only practical remedial measures appear to be cementation of drifts at particularly bad places and working the mine under air lock at a pressure slightly exceeding the normal.

The origin of these gases cannot reasonably be sought in any such explanation as the oxidizing of sulphides and accompanying absorption of oxygen. We believe that they represent the last exhalations from the throat of the extinct Cripple Creek volcano.

**FUTURE OF THE DISTRICT.**—To predict the future yield of any mining district is no easy task; the conditions under which most ores are deposited are as yet too imperfectly understood, and the deposits themselves are usually too erratic in form and distribution to give certitude to such predictions, even when these are based upon a careful study of the history and present condition of a district. Nevertheless, it is part of the duty of the geologists who have officially investigated the Cripple Creek district to interpret to the best of their ability the bearing of ascertained facts upon future development. For such a forecast of the future moderate probability is all that can be claimed.

The largest known ore bodies of the district are apparently confined within a zone which extends from the surface to a depth of 1000 feet. In general, explorations below that depth have been much less satisfactory, as regards quantity of ore, than explorations above. It is certainly true that some large ore bodies as yet show no sign of depletion in depth, and that some good pay shoots have been found at a depth of 1400 to 1500 feet. On the other hand, the number of ore shoots that have been exhausted with increase in depth is considerable.

It is probable that the ore bodies, known or unknown, occurring below the 1000-foot zone are neither so large nor so abundant as those nearer the surface. The discovery and exploitation of these deeper ore bodies is, moreover, beset with increasing difficulties, chief among which is the problem of dealing with the underground water. For these reasons it is unlikely that the zone between the 1000-foot and 2000-foot levels will yield as much as the zone between the surface and the 1000-foot level, but the possibility is not denied that some strong fissures may carry payable ore to far greater depths than those yet attained.

As regards the zone above the 1000-foot or 1500-

\* Abstract Bull. 254. U. S. G. S.

foot level, it is well to bear in mind that it still contains much ore, both as parts of known ore shoots and as yet undiscovered ore bodies. It is certain many of these undeveloped ore bodies will be mined in the near future and that this zone will contribute the most important part of the production.

### Gases in Mines.

Written by W. POOLE, Director Charters Towers, Australia.  
School of Mines.

This subject is a very important and interesting one to all miners and mining communities. There is a large number of gases met with in mines in appreciable quantities, from which the air of the atmosphere is free, or almost so. Almost without exception these gases, whether naturally or artificially produced, pollute or poison the air for breathing purposes. Thus it may be easily seen how necessary it is for those engaged in mining operations to be acquainted with the nature of these gases and the methods by which they may be readily detected, especially those gases which may be given off or formed under ordinary working conditions of the mine.

Air consists principally of a mixture of the elementary gases nitrogen and oxygen, but it always contains in addition some carbonic acid gas, water vapor and a trace of ammonia. The amount of water vapor varies considerably in the air, but, taking a rough average, the percentage composition by measure will stand thus:

Nitrogen .....	77.95
Oxygen .....	20.61
Moisture .....	1.40
Carbonic acid .....	0.04

The atmosphere of mines is subject to various influences which are constantly rendering it less fit for supporting life; not only do noxious gases escape from the rocks of the underground excavations, but the very agents themselves employed in the excavation of the work pollute the air considerably.

Gases sometimes given off in mines are: Carbon monoxide, carbonic acid gas, marsh gas, nitrogen, sulphuretted hydrogen, the vapor of mercury and volatile hydrocarbons.

As before stated, the air of the atmosphere consists principally of nitrogen and oxygen, together with varying small percentages of water vapor and still less of carbonic acid gas.

Oxygen has a density compared to air of 1.1. It is colorless, odorless, tasteless, non-poisonous gas. This elementary gas is the important constituent of air which maintains all ordinary processes of combustion and which maintains life when the air is breathed. Accordingly, processes of combustion become more rapid and vigorous when oxygen is supplied more rapidly or in larger proportion, and respiration becomes insufficient to support life vigorously, or even to maintain it at all, when air is deprived of its oxygen until only 10% of that gas is present.

Nitrogen has a density compared to air of .965.

This gas is the major constituent of air, which it nearly approaches in density. It is colorless, odorless and tasteless gas; it is neither combustible nor does it support combustion, nor is it poisonous. Its province is to dilute the oxygen of the atmosphere on which life depends. Were it not for this dilution, oxidation would be too rapid, and not so completely under control as it is at present. The effect of nitrogen on human life would be to suffocate it if breathed pure, inasmuch as it would exclude oxygen from the lungs.

Nitrogen itself has no life-giving power. Although nitrogen is a very inert element, nevertheless many of its compounds are noted for their very active properties. Among those noted compounds are: Nitric acid, one of the most powerful acids; ammonia, one of the most pungent odors with which we are acquainted; prussic acid, of which potassium cyanide is a compound, one of the most deadly poisons; nitroglycerine, one of the most violent explosives—in fact, most explosives contain a nitrogen compound.

Marsh gas, often called "carburetted hydrogen" or "methane," is a chemical compound consisting of 4 atoms of hydrogen and 1 of carbon. It is one of the chief gases occluded from coal seams; and these gases may, for experimental purposes, be represented by the ordinary coal gas supplied for illumination.

Pure marsh gas is colorless, odorless and tasteless, and is lighter than air. Its specific gravity compared to air is 0.559. It may therefore be poured upwards into a vessel, and an upward movement given to a balance that was before in equilibrium.

Marsh gas diffuses rapidly in the air, forming the explosive mixture known as firedamp.

Marsh gas burns but does not support combustion, and a lamp placed in it will immediately be extinguished. Mixing it with small proportions of air only tends to hasten the burning of the gas. When the mixture is diluted until only 16% of marsh gas is present, it begins to be explosive, but as the proportion of marsh gas in the air approaches 10% the mixture burns with great rapidity—so much so that it is said to be highly explosive. When the proportion reaches 10% the explosion is the most violent possible. If the air increases gradually above this proportion, the mixture becomes less and less vio-

lently explosive, and at last ceases to kindle at all in contact with flame. When the proportion of marsh gas in the air falls below 6%, the gas cannot be fired, but it still shows its presence by burning a pale-blue halo or cap above a flame. Special lamps have been invented for use in coal mines, both for general use and to detect and measure the quantity of this dangerous gas.

Firedamp has been encountered in the old workings of alluvial mines in Victoria. In some instances it is undoubtedly due to the decomposition of mine timbers, and in others to the gradual alteration of driftwood in the alluvial beds. Quite recently an explosion took place in a metal mine in New South Wales, presumably from the same cause.

Afterdamp is the name given to the mixture of gases resulting from an explosion of firedamp. It varies in composition. It usually consists of free nitrogen, steam, carbonic acid, carbon monoxide, and with little or no oxygen. If there is much fine coal dust in the mine, it greatly increases the proportion of the deadly carbon monoxide. The steam that is formed soon condenses.

**CARBONIC ACID OR CARBON DIOXIDE.**—This is often called "blackdamp" or "chokedamp." It consists of 1 atom of carbon and 2 of oxygen. It is 1.5 time heavier than air; may be poured downwards and made to depress one side of a balance that was in equilibrium. It, therefore, tends to accumulate near the floor and in the low places of mine workings. It is the product of complete combustion of carbonaceous material in a full supply of air. It is also the product of the breathing of men and animals and the burning of lamps. It is also exuded from the workings of many mines, both coal and metalliferous. Carbonic acid is colorless, odorless, but possesses a peculiarly sweet taste, which may be detected in the mouth when it is inhaled in large quantities. It is not combustible, nor does it support combustion. Lamps are at once extinguished by it. It diffuses slowly and is a difficult gas to remove in ventilating.

Atmospheric air, as already stated, contains usually about 0.04% of carbonic acid. This proportion has no effect upon the respirability of the air, but if the proportion of the gas increases it will at least reach an amount which renders the air unfit to support life. The extreme limit has been stated to be about 15%, but even less proportions than this in the air cause drowsiness when the air is breathed, and should not be inhaled for any length of time.

Fifteen per cent of carbonic acid in the air will at once extinguish the flame of a candle. If, therefore, in going into a pit or mine workings the candles are extinguished or commence to die out, it is an imperative warning that it is unsafe for men to remain there. It is very fortunate that the amount of carbonic acid which just extinguishes a candle is not immediately disastrous to human life; a narrow margin of safety is thus allowed, giving men due warning to immediately retreat, and it is only courting a fatal result not to obey at once.

Carbon monoxide (often called "whitedamp") is a chemical compound of 1 atom of carbon united to 1 atom of oxygen. It is formed by the incomplete combustion of carbonaceous material with a limited supply of air. It is largely produced in a smothered mine fire; it is also one of the products of blasting. It is also produced when steam is passed through or over glowing embers, hydrogen being at the same time produced. It is in this manner that water gas—a gaseous fuel, composed of hydrogen and carbon monoxide—is produced commercially.

Carbon monoxide is colorless, and has a faint, sickly smell. It is combustible, burning with a light-blue flame. This is the flame often seen over a coal fire. It also forms a faint bluish mantle round a candle flame when the latter is burnt in air containing this gas, but as such a small proportion of carbon monoxide is fatal to life, it cannot be used as a reliable indication of danger.

Carbon monoxide is also a supporter of combustion, being the only mine gas that burns and also supports combustion. This gas has the widest explosive range known to mining except hydrogen. The chief danger arises from its powerful poisonous action, when it is inhaled even in small proportions, probably less than 1%. It is rapidly fatal when breathed. Those who have been poisoned by this gas retain much the appearance of life, the color of the skin being only slightly changed.

This gas is the one to be most dreaded in mine workings, as it gives no warning of its presence, and such a small proportion is fatal. It acts on the human system as a narcotic; in small proportions it produces drowsiness or stupor, followed by acute pains in the head, back and limbs, and afterwards by delirium. In large quantities it is quickly fatal.

**SULPHURETTED HYDROGEN.**—The highly poisonous sulphuretted hydrogen is found in sulphur and occasionally in some metal mines. It is also produced in small quantity in the firing of blasting powder. Its strong and highly offensive smell renders its presence easily detectable. It is thought to be sometimes generated in old mine workings, and is supposed to have been the cause of a death at a mine on the Gympie goldfield about fifteen or sixteen years ago.

**ARTIFICIAL POLLUTION OF THE AIR IN A MINE.**—The pollution of air in a mine is not due solely to

gases introduced naturally from the surrounding rocks, an explosion or gobfire in a coal mine, or fire among the timbering of a metal mine. (In a coal mine the worked out portions are called gobbs; coal dust and slack are often thrown back into the gob. Fires from spontaneous combustion sometimes take place among these gob heaps.)

Various other causes combine to render the atmosphere of the mine unfit for life; among them may be mentioned the following:

(1) Respiration of men and animals in the mines.  
(2) Combustion of the lamps and candles used for lighting the workings.

(3) Absorption of oxygen by pyrites and other minerals.

(4) Putrefaction of timber.  
(5) Explosion of gunpowder, dynamite, etc.  
(6) Stone dust from boring.

(1 and 2) The pollution of the air by respiration and the burning of candles, etc. These sources are self-evident and need no further comment.

(3) Where the ventilation is sluggish the absorption of oxygen by pyrites and other sulphides, or by ferruginous minerals passing to a higher state of oxidation, is sometimes very marked. Not only is oxygen absorbed from the air, making it less fitted for breathing, but the temperature of the workings may also be greatly increased, and thus for two reasons rendering a strong current of pure air necessary for those working there. At Broken Hill the very high temperature in the friable, soft, decomposing sulphides is very marked, and it is very much hotter than in the solid undecomposing sulphides at a lower level.

(4) More important is the foulness of the underground atmosphere produced by the decay of the timber supports. The rapidity with which timber rots underground varies considerably, being very rapid where the conditions are moist and hot, and may be slow where totally submerged under water. The practice of leaving the useless decaying timber to infect the new pieces that are put in turns a level, in some instances, into a hotbed of putrescent matter, offensive to the smell and injurious to the health of the men.

One of the recommendations of the ventilation board in Victoria was that all bark should be removed from the timber before it is sent underground.

(5) It is well known both to miners and chemists that explosives produce noxious gas, despite what makers say to the contrary.

Nitro cotton, or guncotton, should produce by its explosion both carbonic acid, carbon monoxide, hydrogen, and nitrogen; while nitroglycerine produces only carbonic acid, nitrogen, and oxygen. But when imperfectly detonated the resultant gases are more numerous; both explosives will then generate a large proportion of nitric oxide and carbonic oxide, and both poisonous gases are liberated in considerable quantities.

(6) Lastly, we come to stone dust, which is certainly not the least noxious of the impurities of the atmosphere breathed by the miner. It is formed in boring holes for blasting, by the shots themselves, and by the attrition of pieces of rock tumbling about during the ordinary processes of mining. However, the first cause—i. e., in boring—is the one from which the miner is most likely to suffer injury. When he is boring a hole downwards he puts in water, which serves the double purpose of facilitating his work and of preventing any dust from being formed. But when he bores an "upper" by hand, water is not used, and even where machine drills are employed, it is not always that one sees a jet of water under pressure applied to the borehole. The result is that the atmosphere of an end or stope may contain a quantity of fine particles of stone dust in suspension, which are inhaled into the lungs and irritate the air passages. Very probably they are the principal cause of the complaint known as "miners' consumption" or miners' phthisis. This complaint, which is so prevalent among machine drill men, is receiving great consideration on the Rand, in America, and some parts of Australia. The consensus of opinion is in favor of compelling mining companies to provide a water jet for each machine, and also to compel the miners to use it when provided.

From the nature of these before-mentioned gases it will at once be evident how necessary it is to provide efficient ventilation through the working places of mines. As the workings of a coal mine are usually only in one plane, and that but little inclined from the horizontal, it has been found necessary to always provide mechanical means for producing the ventilating currents, which may have to be led 2 or 3 miles from the shaft. In metal mines, on the other hand, there are usually several working places at different levels. The increasing temperatures met with at each lower level will cause an underground circulation of air between the levels if they are connected by passes and winzes. But this alone is not sufficient, as the underground workings must be connected with the surface by two independent airways. This is effected by close-boarding one compartment from the other in a straight shaft, or, preferably, by a second shaft in that or in an adjoining mine to which there are free underground air connections. In a single underlie shaft the downcast follows the floor and the upcast the roof of the shaft. Where

there are both an underlie following the lode and a straight shaft cutting it at depth, the straight shaft will be the downcast and the underlie the upcast.

A fire or an explosion having taken place in a metal or coal mine, it is often necessary for a rescue party to go in to bring out any survivors or the dead bodies of any victims of such a catastrophe.

In a coal mine there are always two main airways, one taking fresh air from the downcast shaft to the furthest workings, and the other, or return airway, conveying polluted air and noxious gases to the upcast shaft. An explosion usually seriously deranges the system of ventilation, the brattices, doors, etc., having been destroyed and allowing the airways to be short circuited. In order to restore the circulation, the fresh-air currents are followed along and the doors and brattices erected or arranged to lead the air to that portion of the mine from which the foul gases are first required to be removed. In coal mines, as the ventilation is maintained by powerful fans, a strong current of fresh air can, therefore, be led into any part of the workings. The heavy foul gases are not, however, readily removed without considerable trouble from some quarters. It may be necessary to proceed at once into such places in making a general exploration or to remove bodies, and in such cases the men going in must be specially protected from the deadly gases that may be encountered. Special apparatus have been invented for such purposes; they are also used in going into dangerous quarters in a metal mine during or after a fire. The ventilation in a metal mine is not so readily restored as in a coal mine, the ventilation usually depending upon natural and not artificial means. The heated poisonous gases may cause a reversal or dislocation of the ordinary ventilation currents. The carbonic acid given off from a fire in a metal mine at first tends to rise, owing to it being greatly heated, but as soon as it cools it tends to settle down into the lower levels, and thus the whole of the workings in a mine or collection of mines may become polluted and dangerous to enter. Even after entering with the downcast fresh air, there is thus danger in meeting foul air, when the main current of fresh air is left to explore some part of the workings where the air current is sluggish.

Several apparatus have been invented to enable men to safely go into foul gases. The apparatus consists of some kind of a helmet or head covering in which the lower part is buttoned down close to the shoulders. The air is supplied from an air pump by means of a flexible pipe, or from a portable reservoir in which it is carried under considerable pressure. The flexible tube is only suitable for short distances.

As a candle will seldom burn where it is necessary to wear a helmet, the wearer should be provided with a portable electric light.

## Mining and Metallurgical Patents.

PATENTS ISSUED JANUARY 31, 1905.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

GRINDING ROLL.—No. 781,043; T. Woodrum, Webb City, Mo.

Crushing roll comprising solid cylindrical body portion having integral terminal hubs, hubs and body portion being pierced by polygonal channel, shaft having polygonal portion to engage channel, polygonal portion terminating with outer faces of hubs, and bolts passing through hubs and shaft.

BLAST FURNACE CHARGING APPARATUS.—No. 781,615; T. McDonald, Youngstown, Ohio.

In blast furnace charging apparatus, hopper, bell arranged to close same, deflector ring outside of bell and independent of movements, and means for vertically adjusting ring independently of bell; and arranged around lower portion of hopper when in in-

operative position, and means for raising and lowering ring.

AUTOMATIC DUMPING ORE ELEVATOR.—No. 781,450; D. B. McTaggart, Butte, Mont.

Combination of frame, car movable therein, car having opening near bottom portion thereof, apron pivoted to car and adapted to close opening when car is loaded, apron acting as discharge chute for material passing from car, when apron is moved upon pivot to permit such discharge, elbow lever pivoted to car and designed to engage with projection formed on apron for locking latter, and relatively long bearing strip for automatically tripping locking lever to its disengagement from projection.

PROCESS OF TREATING ZINC SULPHIDE ORES CONTAINING IRON.—No. 781,133; C. E. Dewey, Denver, Colo.

Process for treatment of zinc sulphide ores containing iron, consisting first in roasting ore, whereby zinc is converted into zinc sulphate and zinc oxide, and iron present, into ferric oxide as far as practicable; second, placing ore thus prepared in water; and third, maintaining ore in suspension in solution by introduction of sulphurous gas whereby zinc oxide present is formed into zinc sulphite, and latter into zinc sulphate by reaction with ferric oxide.

BLASTING APPARATUS.—No. 781,619; S. Rogers, Anniston, Ala.

In blasting apparatus combination with metal tube provided with electric heating chamber at its inner end, of closed casing surrounding same, composed of fragile material, and adapted to contain liquid which when heated to proper temperature will disrupt

casing, all constructed and arranged to operate as and for purpose set forth.

METHOD OF TREATING ORES.—No. 781,520; H. A. Hogel and H. A. Hogel, New York, N. Y.

Method of treating ore to bring metallic particles thereof into solution quickly, which consists in pulverizing ore, then subjecting it to action of solution containing suitable chemicals and intensifying and quickening solvent action of solution upon ore by atomizing mixed mass under influence of heat, and agitating mass by means of currents of air or steam.

ROCK DRILL.—No. 781,241; W. C. Stephens, Cambridge, England.

In rock drill, combination with working cylinder and reciprocating piston therein, of distributing valve casing for cylinder provided with air locks, and distributing valve in casing, ports in cylinder connected with passages extending to air locks, adjustable bushings in ports and movable valves having portions for directly engaging bushings and wearing portions projecting into cylinder in path of piston, whereby wear on valves and piston may be compensated by adjustment of bushing.

ELECTROMAGNETIC ORE SEPARATOR.—No. 781,077; E. Langguth, Euskirchen, Germany.

In magnetic separator, combination with pole pieces, of armature rotating between pole pieces and having windings, shield of magnetic material mounted directly on armature and rotating therewith, means for feeding material to be separated to armature, and means for collecting separated material.

## Gold Mining in Rhodesia.

NUMBER II.

Written for the MINING AND SCIENTIFIC PRESS by F. C. ROBERTS.

**FINANCIAL CONSIDERATIONS.**—The British South Africa Co. formerly had the right to demand up to 50% of the vendor's interests in any mining flotation, but the right was seldom exercised up to its fullest extent; this has now been reduced to 30%.

This right is generally satisfied by the transfer of a certain number of shares upon the formation of a company.

The *modus operandi* obtaining in Rhodesia, and adopted by practically every financial house operating here, contains many features which to those unacquainted with the local conditions and market considerations would appear to cast an unnecessary burden upon the gold mining companies in the shape of heavy capitalization.

The capitalization of many of the mining companies which have elected to operate in this country has been the subject of adverse criticism by most visitors here, and no doubt adequate grounds are offered for such criticism; but when all of the circumstances attending the handling of a mining venture in Rhodesia are duly weighed, it would seem to lessen the responsibility of some of the "parent" companies.

A mining claim in Rhodesia embraces an area 150 feet along the strike of the vein or old working by 600 feet, measured 300 feet from a center line through the outcrop or old working, hence ten claims constitute a block or location, 1500 feet by 600 feet, as defined by the United States mining code. The mineral ordinance of Rhodesia is really only a modification of the United States law.

What is termed the "parent" company in Rhodesia is a limited liability company, with a capital of from \$150,000 in small concerns to \$4,850,000 in the larger houses, formed for the purpose of acquiring mines, lands, farms, etc., the latter being largely dealt in in order to secure the timber in close proximity to the mining interests, which, up to the present, constitutes the only fuel in the country. The company pays a royalty of \$1.20 per cord to the farm owner.

The number of claims controlled by these parent companies varies from 100 in small concerns to 5000 in larger companies.

The object of the parent company is to carry out a system of prospecting and development work upon their more favorable interests, with a view (where the conditions warrant) to placing independent properties upon the market for flotation into "gold mining companies." It is obvious that in a country where development expenses are very high there must be a limit to the extent to which this work can be extended, if more than one property is to be dealt with, for if an attempt were to be made by the parent company to develop from eighteen months to two years' ore over a reasonable width upon a number of interests at the same time, it would be impossible to finance the work; hence it is clear that the gold mining company faces very grave responsibilities, and therein lies the key to many early liquidations. The problems with which the parent company is faced are as follows:

A—Capital and shares involved in purchase of property.

B—Capital involved in prospecting and development work.

C—Capital involved in installation of temporary surface equipment.

D—Interest accumulating upon capital invested.

The chief considerations of the gold mining company are as follows:

1—Capital involved in purchase of property from parent company.

2—Capital involved in development work.

3—Capital or shares involved in commutation of British South Africa Company's rights.

4—Capital involved in purchase and erection of plant.

5—Capital or shares involved in making provision for possible extension of plant.

Assuming a width of vein of 30 inches and the ore bodies not too scattered, it would be necessary to make provision for an expenditure of no less than \$363,750 in order to bring a property to the milling stage, and equip it with a 20-stamp mill with cyanide annex, etc. This expenditure should, under ordinary circumstances, enable one to develop from eighteen months to two years' pay ore.

As a matter of fact, no mine in this country should begin the reduction of ore with less than three years' ore in such a state of exposure as to be reasonably counted upon to return a margin over and above the estimated operating expenses, as it is next to impossible to keep the development work as far ahead of the reduction plant as the constantly fluctuating and inefficient labor supply demands.

The money required for the equipment of a mine with a modern reduction plant is as important a financial consideration as the provisions necessary for extending the development work.

(TO BE CONTINUED.)

## MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

## ALASKA.

At Silver Bay, on Baronof island, the Chicago-Sitka G. M. Co. has struck a 22-foot vein of free milling ore, after driving 2200 feet of tunnels and drifts. H. A. Bowers, the president of the company, has left Alaska to confer with Chicago stockholders as to equipping the property with a mill. The Escot mine, near Wrangell, has been bonded to H. H. Hunter of Juneau, who has men at work at the mine.

The Triple M. & Ditch Co. of Seattle, Wash., has been formed to build irrigating ditches and develop mining properties in the Kiguarok district. F. W. White is president, C. E. Keen vice-president and general manager, E. E. Gledhill secretary and treasurer, with headquarters at the Oriental Block, Seattle, Wash.

Hills & Reck are opening a mine in the town of Juneau, where they are developing a lode on the mountain side and have crosscut 42 feet of fine looking ore. They intend to continue the work and will have a mill test made.

A new quartz discovery is reported by J. T. Martin and others, 25 miles southeast of Windham on the mainland, says the Juneau Dispatch. This is thought to be an extension of the main zone. If so, it will add 30 miles of unexplored territory to the already proven territory, making 170 miles of a mineralized belt.

## ARIZONA.

## Pima County.

In the Empire Gulch, on the north side of the Santa Rita mountains, near Patagonia, M. Ensenburg is putting in a plant to work placer ground at the forks of Empire and Chispa gulches. The outfit will consist of a steam shovel and a gold washing machine. G. L. Smith of Cincinnati, O., is superintendent.

## Santa Cruz County.

Regarding the Tyndall district, in the Santa Rita mountains, the Nogales Oasis reports that at the Wandering Jew mine, near Patagonia, M. Lulley and associates are running a tunnel to cut into the ore body at a depth of 100 feet below the bottom of the 100-foot shaft. The tunnel, which will reach the ledge at a distance of 348 feet, is now in 75 feet.—J. Peterson and G. Clark are working the Viceroy mine, in Squaw gulch, having run a tunnel 400 feet on the ledge.—In the properties of the Happy Jack M. Co., W. H. Barnett manager, the main tunnel is in 735 feet and crosscutting is being done.

At the head of Josephine canyon J. Kane is working the Santa Cruz and Tia Juana mines, in which there is a 20-foot ledge, with a 3-foot paystreak of molybdenite.—The Eureka mine of the Salero Mines Co., W. E. Balcom superintendent, has a tunnel 500 feet long and is steadily shipping ore.—The litigation over the Bland group of mines has been settled and they will be developed by W. P. Savage of Patagonia.—F. C. Lincoln, formerly instructor in the New Mexico School of Mines, has leased the properties and concentrating mill of the Arizona G. & C. Co. at Patagonia, and has resumed operations. At the Trenton mine the water has been pumped out of the 150-foot shaft to clear the 110-foot level, and the level has been extended, cutting into a shoot of good ore showing galena, gray copper, etc. The concentrator will be overhauled and set to work.—Superintendent Reed of the El Plomo is running a 2100-foot tunnel and will sink a 700-foot shaft from the top of the ridge. He will put in an air compressor, dynamo, hoiler, engine and machine drills. J. N. Curtis is general manager. A road is being built to connect the mine with Patagonia.

## Yavapai County.

In the Prescott Courier, J. J. Sanders reports that the mineral production of Yavapai county for 1904 amounted to \$5,939,859.79, as follows: Gold, \$1,428,233.63; silver, 325,619 ounces; lead, 356,619 pounds; copper, 30,920,119 pounds.

The Bradshaw Mountain Copper M. & S. Co. completed a tunnel 2200 feet in length into their mines at Middleton, cutting five veins averaging from 16 to 85 feet in width and carrying good values in copper, gold and silver. A short time after this company acquired the Val Verde smelter, a fire destroyed the plant. They have since raised \$500,000 for a new plant.—The Poland tunnel, over 8000 feet in length, was completed early in the year.—Sixteen miles of railroad were built in the completion of the Bradshaw Mountain road to Crown King. The completion of this railroad has greatly stimulated the production and development of the mines in that section of the county.—The United Verde Co. operated its mines and smelters at Jerome steadily during the year, and erected a 250-ton smelter on the Equator mine, 8 miles from Jerome.—The Treadwell M. Co. erected a 250-ton smelter.—The Congress Gold Co. confined the greater part of their work for the year in doing development work.—The Octave mine at Octave is being worked through two shafts, one 1850 feet and the other 1750 feet deep.—The Yeager Canyon Co. erected a 60-ton concentrating plant.—The Model M. Co. put a 50-ton mill with Wilfley concentrators on the McCabe mine, east of Prescott.—The Gladstone mine, near the McCabe, has been worked during the year under a lease and has been producing steadily.—The Little Jessie, near Mayer, has been repaired in mine and mill.—The Stark G. M. Co. completed a 10-stamp mill and 30-ton cyanide plant on the Hidden Treasure mine.—The White G. M. Co. put up a 20-stamp mill and a cyanide plant for the treatment of their ores.—The Monica mine at Kirkland erected a 10-stamp mill with a 30-ton cyanide plant.

The mines of Yavapai county are equipped with milling and smelting machinery capable of treating 5070 tons of ore daily. The smelting capacity is 2750 tons and the milling capacity is 2320 tons.

## Yuma County.

The White Eagle M. Co., working gold and copper claims at Empiro Flat, intend to build a smelter at the mine when the branch of the Santa Fe, being constructed from Congress Junction to the Colorado river, is finished, probably about the first of May. J. H. Watson is superintendent.

## CALIFORNIA.

The following table shows the yield and value of mineral substances of California for 1903, as per returns received at the State Mining Bureau, San Francisco, in answer to inquiries sent to producers:

Mineral.	Quantity.	Value.
Asphalt, tons.....	41,670	\$503,050
Bituminous rock, tons.....	31,914	53,100
Borax (crude), tons.....	34,430	691,400
Cement, barrels.....	640,888	968,727
Chrome, tons.....	150	2,250
Chrysoprase.....		500
Clays—for pottery, tons.....	60,972	49,097
Clays—for brick, M.....	214,403	1,060,546
Coal, tons.....	93,025	265,383
Copper, pounds.....	10,113,861	2,520,997
Fuller's earth, tons.....	250	4,750
Glass sand, tons.....	7,725	7,825
Gold.....		16,471,264
Granite, cubic feet.....	408,625	678,670
Gypsum, tons.....	9,014	40,441
Infusorial earth, tons.....	2,703	16,015
Lead, pounds.....	110,000	3,960
Lime, barrels.....	460,587	418,600
Limestone, tons.....	125,919	163,888
Lithia mica, tons.....	700	27,300
Macadam, tons.....	605,185	436,172
Manganese, tons.....	1	25
Magnetite, tons.....	1,361	20,515
Marble, cubic feet.....	81,024	97,354
Mica, tons.....	50	3,600
Mineral paint, tons.....	2,370	3,720
Mineral water, gallons.....	1,978,340	558,201
Natural gas, M cubic feet.....	120,134	75,237
Paving blocks, M.....	4,854	134,642
Petroleum, barrels.....	24,340,839	7,313,271
Platinum.....		1,052
Pyrites, tons.....	24,311	94,000
Quartz crystal.....		1,908
Quicksilver, flasks.....	32,094	1,335,654
Rubbe, tons.....	1,610,440	1,237,419
Salt, tons.....	102,895	211,365
Sandstone, cubic feet.....	353,602	585,306
Serpentine, cubic feet.....	99	800
Silver.....		517,444
Slate, squares.....	10,000	70,000
Soapstone, tons.....	219	10,124
Soda, tons.....	18,000	27,000
Tourmaline.....		100,000
Turquoise.....		10,000
Total value.....		\$37,750,040

## Amador County.

The State Supreme Court has affirmed the lower court's decision in a suit entitled Central Eureka M. Co. v. the East Central Eureka M. Co. A man named Toman is a joint defendant. The Central M. Co. gave Toman a deed to the agricultural rights on the land, lying to the eastward of the lode and beneath which the lode dips. Toman sold his right to the East Central M. Co., which also claimed the right to the minerals. The lower court held that the Central company had not disposed of the mineral right, and the Supreme Court has affirmed the ruling.

## Calaveras County.

D. P. Gray is ground sluicing on the Hagerman ranch, near San Andreas, on the Calaveras river. There are thirty acres of gravel, lying between the river and the adjacent hill side. Much of the high bar gravel of this vicinity has never been systematically prospected, but is known to contain gold.

## El Dorado County.

The Union M. & E. Co. at Georgetown have elected T. A. McCullough president, G. F. Randall vice-president, J. G. Tillar secretary and treasurer and J. M. Isgrig general manager. The mine is at Fort Hill.—M. W. Sargent is preparing to hydraulic on the Mameluke Hill, near Georgetown.

A. P. Grasser has put a hoist and gallows frame on the Zantgraf mine, near Auburn.

## Inyo County.

In the Sherwin district, 20 miles northwest of Bishop, B. E. & J. Sherwin have bonded the Casa Diablo mine to a Chicago, Ill., company, of which the treasurer is W. W. Smith, and the resident manager and superintendent is C. A. Fohrman of Chicago. A 1000-foot tunnel is being driven and arrangements are under consideration for a 30-stamp mill and cyanide plant.—A. E. Vandercook, manager of the Southern Belle M. Co. near Owensville, is adding five stamps to the mill and will put in a dynamo to furnish power for lights and for two electric hoists at inclines below the tunnel level.

## Kern County.

Work has been started on the Bully Boy mine, near Randshurg, by T. W. Atkinson. There is a shaft down 98 feet. A new shaft is being sunk.

## Nevada County.

The Polar Star mine, at Grass Valley, will probably be reopened by W. W. Byrnes. It is intended to replace the present wood-burning system with oil burners. T. Warden has been appointed superintendent.

## Placer County.

The Paragon mine at Bath is working a number of men and gold is being taken out. Men are at work at Eagle Bar and also at the Buckeye. The Baltimore is working twelve men.

## San Bernardino County.

(Special Correspondence).—A. H. Cohn, representing J. R. De Lamar, has bought the newly discovered group of mines 25 miles north of Furnace on west side of Grapevine range, at the north end of Death valley, paying \$25,000 on a \$150,000 contract. It is stated that the vein can be traced through four locations and is 25 feet wide. Ballarat, Feb. 5.

## Shasta County.

O. B. Perry, head of the Indiana Dredging Co. operating at Oroville, Butte county, has acquired a half interest in the Detroit & California G. M. Co., dredging at Horse-town. The company intends building another dredger right away.

## Sierra County.

W. O. Frost found a nugget of gold last week at his

mine in Hungry Mouth ravine, weighing 4 ounces. A short time since he found one weighing 12 ounces near the same place.

#### Siskiyou County.

The Morrison & Carlock mine, at Quartz Valley, is working forty-five men; 600 tons of ore are being crushed each month.—The McKinley quartz mine, at Humburg, is being worked with twelve men.

The gravel mines about Oro Fino are preparing to begin the season's hydraulic mining. There is enough water now for most of these mines. Placer ground is being tested by means of a well-boring outfit.

#### Tuolumne County.

(Special Correspondence).—The Clío mine, near Jacksonville, has resumed operations. The mine is equipped with a mill and other necessary machinery. E. Parr is foreman.

At the Soulshy mine, at Soulshyville, sinking has been resumed in the Pennsylvania shaft, and until the 500 level is opened the mill will be idle. The Pennsylvania shaft is sunk on the east branch of the vein. The old workings are 800 feet deep and are flooded. There has been some talk of unwatering the workings which have been abandoned for years. There is said to be good ore left in the old workings, and indications are that the ore shoots continue to the northward beyond the limits of these workings.—The Gross mill at Tuttletown is crushing ore from that mine.

Sonora, Feb. 6.

Rich rock from above the 400-foot level is being run through the mill at the Mohican mine, near Groveland.

The Minnehaha mine, on the Tuolumne river, a few miles from Groveland, has been sold by W. Vincent to T. J. Crowley.

E. L. Flower and I. B. Watson have inspected the McPherson mine, near Jacksonville, with a view to purchase.

At a recent meeting of the stockholders of Densmore M. Co. the following were elected officers and directors: F. W. Street, president; J. B. Pownall, vice-president; C. Hampton, secretary; J. A. West, treasurer; W. D. Bannister, A. J. Crowell. The mine is 2 miles north-west of Columbia. A. Crowell is superintendent.

F. D. Nicol has sold to H. Shaw a one-half interest in his quartz mine situated at Saw Mill Flat.

A company of San Francisco men are operating the Nigger Hill mine, on the J. Moore ranch, near Columbia. F. Stephenson is in charge of the work and says prospects are good.

E. M. McCutchen and D. M. Garner of Groveland recently bought the Eagle Bluff mine, on the Tuolumne river. Work will be commenced on this mine immediately.

Ore is being stoped from the 300 and 400-foot levels of the Soulshy mine, near Soulsbyville. —The Fair Oaks mine on Provost mountain, 3 miles east of Carters, shows a free-milling vein of ore. The tunnel has been driven 100 feet. The mine will be equipped with facilities for sinking and treating the ore. —At the Draper mine and mill, near Carters, Superintendent Herthel is blocking out the ore bodies. The ore sent to the mill is taken out in sinking and running the various drifts. Additional surface facilities are needed to carry on development work to a greater depth, and the installation of a new and larger hoisting plant has been decided upon. The mill capacity will be increased by five stamps.

#### Yuba County.

At Rackerby, J. E. Spencer is sinking a shaft and putting new machinery on the Abbott mine.

### COLORADO.

(Special Correspondence).—Placer mining is on the increase in different sections of the State, and each year sees important changes in the development of placer ground. The placers near Alma and Fairplay, in Park county, have been consolidated and many improvements are contemplated during the coming summer. The water supply is the vital question to placer mining and unless some scheme is devised to retain the surplus water towards the end of the season the supply is usually cut short. The Snow Storm Co. is making preparations to increase their water supply by a series of reservoirs or other means to hold the water back. It is thought that some of the small lakes near the source of the water supply will be tapped and so arranged that water can be taken from the lakes as needed later in the season. From reports received the snow fall has been quite heavy so far this winter, which means much to the placer companies.

Some good sales of mining property have been reported recently. The latest of importance comes from Leadville, which will have a good effect on that district. The property reported sold to Eastern capitalists is located on Rock hill, near the Reindeer, one of the Rock hill producers.

Denver, Feb. 6.

In his official report to the directors and stockholders of the Portland mine at Cripple Creek, which was presented at the annual meeting in Council Bluffs, Iowa, on the 6th inst., Mine Manager F. M. Kurie, speaking of the mining methods, made the following statement: For some time past it had been the practice to narrow the stopes down to the richest portions of the veins. This is certainly a good way to make a splendid financial showing, but in the end it is very bad for the mine, for the rich ore is usually but a small part of the veins and its exclusive mining, if continued, would shorten the life of the mine materially. We have widened all the stopes to the extreme limits of the pay ore, everything being taken out that could be made to yield a profit, even if it amounted to but a few cents per ton. This has given rise to some very difficult mining problems. In cutting into the walls of the old stopes, very large blocks sometimes become loosened, and the greatest skill is required to prevent serious caves and accidents. The system used in working the veins in the volcanic area has reached such a state of perfection that we can now work at a profit very low grade ore bodies that were until recently considered worthless. The ore is first broken as coarse as possible by breast stoping, i. e., the holes are drilled horizontally into the rock. The object of the

coarse breaking is to avoid, as far as possible, breaking the barren rock to screenings. The higher grade faces are then cobbled off and the waste rock is left in the stopes. This necessitates rough sorting in the stopes. While the amount of development work done in 1904 was a little less than in 1903, being 3 miles 2704 feet, against 4 miles 2353 feet, a difference of 2811 feet, the results of 1903 are not to be compared in any way with those of 1904. An estimate made by Mr. Williams, our mine engineer, a short time ago, showed that for each ton of ore mined in 1904 more than three tons were added to the reserves. This estimate was based on actual measurements of the length, width and height of the blocks of ore. Where a vein had been opened on a level alone the ore was estimated as extending but 50 feet above and below the level. Where the development work had not gone far enough to show the extreme limits of the ore, it was considered as extending but a few feet beyond the faces. Without a doubt the most important find was the Queen of the Hills vein in the granite area to the southwest of No. 1 shaft. This vein has been developed on the 200, 400 and 500-foot levels of No. 1 shaft and was recently cut on the 600-foot level. It is therefore known from the surface to the 600-foot level. Nineteen hundred and three was a record-breaking year in mine costs up to that time, but 1904 shows these costs to have been lowered about 15%. Close supervision, and that alone, is the secret of low cost. The most salient features of the report of Secretary and Treasurer F. G. Peck are as follows:

#### RECEIPTS.

Ore.....	\$2,598,724 84
Insurance.....	11,401 49
Rent.....	300 00
Transfer fees.....	13 50
Royalties.....	3,531 23
All other sources.....	2,687 80
Total receipts.....	\$2,616,658 86

#### EXPENDITURES.

Sampling.....	\$ 5,137 45
Treatment.....	702,860 36
Railroad.....	128,532 88
Permanent equipment.....	8,190 54
Portland mine account.....	137,877 97
General expense.....	68,782 57
Salaries.....	17,724 99
Legal expense.....	19,015 33
Office expense.....	12,051 24
Fuel.....	41,830 51
Explosives.....	50,818 04
Mine supplies.....	41,592 84
Pay roll.....	567,715 42
All other expenses.....	124 42
Total expenditures.....	\$1,802,247 21
Net profits.....	\$814,411 65
Total.....	\$2,616,658 86

The following is Mr. Hills' report on the labor troubles: "The economic feature of the labor troubles has been a great surprise to me. With any change in the majority of the persons on the payroll or any violent change in the policy of management, it is naturally expected that the costs will suddenly rise, temporarily, whatever may be the final result. The raise in cost of production came in June, as was to be expected. With an enterprise requiring a somewhat complicated system of management and employing more than 500 men, I should have been willing to grant a full year's time to return to normal conditions. Yet your management, paying exactly the same wages as before, succeeded in reducing the costs before October 1 to a point even lower than before the change."

The following are the figures by months:

	Cost Per Ton Crude.	Cost Per Ton Shipped.	Cost Per Ounce Gold.
1904.			
January.....	\$ 2 5003	\$9,3465	\$7,9578
February.....	2 3702	8 4150	6 7204
March.....	2 4832	8 7405	7 5195
April.....	2 4707	8 4725	7 0334
May.....	2 3847	8 4650	7 2604
*June.....	2 8493	9 9140	6 7908
July.....	22 5431	8 7048	6 5307
August.....	2 5941	9 0528	6 7021
September.....	2 6572	9 1265	7 0256
October.....	2 1835	8 1275	5 7320
November.....	2 3338	7 5592	5 7877
December.....	2 1087	7 1841	5 0676

\*Twelve days closed; reopened June 21 with non-union labor.

This, I think, reflects more than ordinary credit on the manager, the superintendent and the corps of assistants. With the possible exception of some small properties which employ say less than fifty men, I doubt whether any mine in the district can show as good a record for the same period.

#### Boulder County.

R. S. Billings, general manager of the Golden smelter, reports having "blown in" another furnace, and that the plant is now smelting 300 tons of ore daily. Ore is now coming from all portions of the State. New shipments are added to the list daily, many of whom were unable to work their properties heretofore. A number of properties have resumed and now find a market for their low-grade mineral which could not be produced heretofore except at a loss.

#### Clear Creek County.

L. W. Vidler, manager of the Vidler tunnel at Georgetown, will build a power house, hoarding house and blacksmith shop and put in machinery and power drills.

#### Fremont County.

The Royal Gorge Coal Co., a few miles south of Canyon City, has let a contract for a 400-foot slope to J. Arthur. When the new slope is down the company will be able to raise 400 tons per day. In about ninety days the railroad branch will be completed to the mine and shipments can then be made more conveniently. The company will also do considerable building. President Bettis will put in an electrical equipment, the power to be furnished by the Canyon Electric Power Co. When these improvements are completed the Royal Gorge will be the leading mine in the county.

#### Garfield County.

The Colorado Power & Irrigation Co.'s plan to supply 40,000 H. P. from the Grand river from the headgate at the upper end of Shoshone falls, 10 miles up the canyon from Glenwood, the water to be conveyed through steel flumes, in connection with tunnels, to the site of

the power plant, which will be conveyed 2.65 miles below the headgate. A concrete wing dam, constructed diagonally across the river at the head, will turn the entire body of the stream into the flume at low water, but at higher stages the surplus will pass over the dam without causing any back water. The flume will have a fall of 4 feet to the mile. At its lower end it will be 225 feet above the site of the plant, and at this point a header is to be constructed, from which the water will have an almost vertical fall to the plant at the river level below. Electricity will be generated and carried by a double system of wires to Leadville and surrounding mines.

#### Gilpin County.

The United M. & E. Co., while sinking the 210-foot shaft on the Modoc in Quartz hill district, near Central City, struck a vein containing ore which assays 8½ ounces of gold to the ton, says the Gilpin Observer. The company operating the mine have had a lease and bond since October, during which time sinking on an extensive scale has been done. This is the first vein that has been struck, all the other strikes being deposits or pockets. The Modoc is near the Roderick Dhu, San Juan and Climax, all of which have good records as big producers. It was idle two years prior to the time the lease and bond was taken by the United Co., but before that had been worked about ten years. The manager will ship several carloads of the high grade ore. C. Soper is superintendent of the Modoc.

C. Houser & Co. have started up the Gardner property on Quartz hill and are working in the 350-foot level and will shortly commence work at the bottom of the shaft which is down 1000 feet. The Gardner is one of the oldest properties in the Quartz Hill district. Houser & Co. will commence shipping next week.

The Russell mine, owned and operated by the Russell Mining Co., in the upper end of Russell gulch, near Central City, has been closed down temporarily. The machinery in this mine being inadequate for the hoisting of the ore, the company has decided to put in a new and larger plant. This does not include the leasers, as they will still continue to work the mine, but development work will cease for a short time. The Russell has been a good producer and in the past couple of weeks a fine body of ore has been uncovered which shows values of \$60 per ton. In shaft No. 1 the ore runs \$25 to the ton. This is also a new body opened up.

The West Pewahic belongs to this group and is reported to have produced \$5000 in the past three months, with about 60 tons of ore to receive returns from, which will bring it up to about \$6000. This mine has been worked with a whim. These mines are managed by Mr. Paxton.

#### Gunnison County.

(Special Correspondence).—E. E. Connery, O. J. Mudd, W. J. Baird and J. Schriener Sr., of St. Louis, who, with D. C. Tohin of Leadville, Colo., who recently bought the Continental gold mine, at Vulcan, Colo., last week visited the properties and report important development under way and an increasing tonnage of gold quartz going to smelter at Pueblo. They will soon install a modern amalgamating and cyanide mill.

Vulcan, Feb. 6.

The Jim lode at Carbonate is under the management of J. Stephenson, who has opened up a strong vein. A tunnel is being driven to cut the vein 300 feet deeper. The old bore is in 175 feet. The new tunnel has recently cut a 4-foot lead of talc and mineralized matter. The Jim is owned by Stephenson, Tarkington and Fry.

The Polaris tunnel in Last Chance gulch, owned and operated by a Pittsburg syndicate, is in over 150 feet and has a promising showing. Dodge and Fry, who have a contract for driving the tunnel 100 feet, have nearly finished their job.

The shaft on the Homestake group is to be sunk deeper. The shaft is now 50 feet on a good vein. All of the ore is of a good grade and it is believed that with depth the property will become a regular shipper. High assays in gold and silver are being obtained from the ore mined. H. G. Leavitt of Omaha, Neb., has an interest in the mine.

Good veins are being cut by the tunnel being driven on the Ninety-Four group in Dutch flats. Little attention is being paid to these veins, however, as the principal object in driving the tunnel is to open up the Raymond vein.

#### Hinsdale County.

Mining is beginning to have a decided upward turn in this part of the San Juan, and although the spring season is still some distance away, preparations are under way for the opening up of some of the old-time producers.

Zacharias & Whinnery have a bond and lease on the St. Jacobs mine, and will put the old workings in condition to prosecute development work on the old shoot. The St. Jacobs is at Carson camp, 16 miles southeast of Lake City. About the years 1887 to 1892 this property, though but a prospect, produced high grade sulphuret ore to the amount of nearly \$150,000, but with the slump in silver the property closed down. Since then practically no work has been done on the St. Jacobs.

E. P. Jordan, cashier of the Miners and Merchants' bank at Lake City, has the Belle of the West mine and the Golden Fleece mill and the combination gives every promise of being a good money maker. The Belle of the West was closed down in 1893. Since then this country has been the scene of many building operations with concentrating plants as the chief industry. The mill is located at the mouth of the Belle of the West workings, and the ore in that vein is a simple one for concentrating.

The Fleece mill will for the present be worked on Belle of the West ore. The newly organized Fleece company is planning work to locate the bonanza shoot. All work during the year will be in that direction.

#### Lake County.

One of the largest zinc buyers in Leadville says that before the current year passes ore carrying as low as 15% zinc will be treated at a profit. There is not a mine in the camp that cannot produce large quantities of 15% zinc ore. Twenty-six per cent zinc ore is now being han-

dled at a good profit and treatment methods are being improved right along.

#### Sammit County.

The vein in which the new tunnel of the Old Union M. & M. Co. is being driven is reported having 2 feet of lead-silver ore that will show a smelting value of \$20, beside the streak of high-grade 17.12 ounces gold ore. The gold ore also carries eleven ounces in silver to the ton and good progress is being made in driving the tunnel, which will be equipped with a double track as soon as it reaches the ore bodies which are opened up by drifts from shaft No. 1. The machinery is going in the company's 100-ton concentration mill.

The Carbonate group on Mount Baldy, above timber line, has out a carload of auriferous carbonate of iron, which also carries good silver and lead values. The mine is operated through the lower tunnel. The ore generally runs from one and one-half to three ounces in gold per ton, with lead and silver values making it worth from \$80 to \$100 per ton.

J. Madron and L. Lipp, who are drifting on a small streak of high-grade smelting ore from a new shaft sunk in the Germania group on top of the "saddle" of Little mountain, are operating under a sublease from Mayor Kaiser of Breckenridge. C. Kaiser and J. B. Conrad are sinking a shaft a short distance east of the place where former Lessees Kilnefetter and West took out about \$50,000 worth of ore at the "grass roots." Their shaft is down 40 feet in quartzite. They are expecting to strike the continuation of the flat vein on the dip. A shipment of a carload of ore made last month from their lease netted Madron and App \$997.

The Mineral Bolt and Lucky mining property, located on Mineral hill, 2½ miles from Breckenridge, on the north side of the French gulch placer, has been sold by S. B. Wright of this city to the Beaver Creek G. M. Co., now operating in Buckskin gulch and on Silverheels in Park county. The Breckenridge property consists of twelve lode claims and two mill sites, and is equipped with a mill of 100 tons capacity. There are more than 3000 feet of tunnels and drifts on the property and nearly 2000 feet in shafts. The longest tunnel is 1700 feet and cuts the four large veins running through the hill. Only one of these veins has been partially explored, which opened up large bodies of ore delivered to the mill through the long tunnel. The Beaver Creek G. M. Co. is composed of capitalists of Chicago, Columbus and Mount Vernon, Ohio, and Pittsburg, Pa. F. A. Yauger is general manager.

#### Teller County.

The production of the Cripple Creek mills and smelters for January, as reported by the News, was:

	Tons.	Value.
United States R. & R. ....	25,000	\$ 250,000
Smelters .....	10,000	650,000
Portland .....	8,500	255,000
Economic .....	2,900	101,500
Doreas .....	3,400	108,800
Wild Horse .....	2,500	15,000
King & Craig .....	500	5,000
Other cyanide mills .....	1,000	6,000
Totals .....	53,800	\$1,891,300

The Cold Coin at Cripple Creek is to be unwatered to the 1200-foot level, the bottom of the shaft, in hopes of finding the high-grade shoot opened on the 1100-foot level.

Four feet of ore has been opened in a body of undetermined length by the J. C. Hamby Leasing Co. in the Castle Garden slope of the Ramona, on the west slope of Bull hill. The discovery was made at a depth of 144 feet, on an extension of the War Eagle vein. The body has been followed for 25 or 30 feet. Two or three carload shipments have been made. Settlements indicate \$60 in gold to the ton.

Operation of the washing plant on the Jo Dandy mine of Raven hill have begun under the direction of Smith & McLeod, lessees. It will handle 100 tons of ore and waste daily. Preparation for the work has been under way for several weeks. An ore house has been built and a washer installed. A tunnel has been run into the dump. As much of the ore of the property had a value of \$55, it is believed that good returns may be obtained from handling the deposit. There is enough rock on hand to maintain the venture for a year or longer.

At Stratton's Independence mine large electric lights have been installed to enable the carpenters to continue their work of building the new ore house to replace the one recently burned. Three shifts of carpenters are employed and it is estimated that this work will take seven weeks to complete. The new ore house will contain ten ore bins.

There is much prospecting in the upper portion of a large number of mines in this district. The inducements are greater, in that more ore is found nearer the surface, and the expense is trifling as compared with deep mining. Most of this work is being done by leasers. As the work of development in the mines of the district extends, the distribution of ore bodies and their relation to one another is better understood, and, as a consequence, strikes are of more common occurrence than heretofore.

The Gold Sovereign M. Co. resumed possession of their property, the lease held by the Cripple Creek Gold Temple Co. having expired. The last shots put in by the lessees revealed between 6 and 8 feet of ore which runs from six to twelve ounces in gold to the ton. The streak of rich ore is in a shoot 20 feet wide.

The leasing company has been given three days in which to take out the ore broken by the final shots, and then the Gold Sovereign will operate the property on company account.

F. Buck and an associate have subleased the Twin Sisters and Mohawk Belle properties on Raven hill and are pushing development on the claims.

Shortly after entering the Mohawk Belle the lessees struck ore of high grade, some of the assays showing \$1020 worth of gold to the ton. This was in a streak of limited width. Three or four feet of ore lying alongside the streak showed metal to the value of \$25 a ton under the same test. This was at a depth of about 145 feet.

F. Buck has leased two properties on Raven hill and is making preparations to put in a cyanide plant. The

ground is that known as the Twin Sisters and the Mohawk Belle, on the east slope, which he and an associate have obtained under sublease from the lessee. Fifty tons is the proposed capacity of the plant. It is calculated that treatment can be accomplished at a cost of \$1.50 per ton.

#### IDAHO.

##### Blaine County.

At the War Dance mines of the Wood River Zinc Co., Superintendent F. W. B. Johnson is surveying for the mill gradings. Accommodations have been completed for the men.

##### Idaho County.

The Moose Creek placers at Newsome creek, near Grangeville, have been sold by the Moose Creek Placer M. Co. to the Mercantile Finance Co. of Chicago. The negotiations were conducted by C. P. Richardson, president and manager, and T. H. Bartlett, secretary and treasurer, for the Moose Creek company, and T. Rhodus of Chicago for the Mercantile Finance Co.

A rich strike in quartz is reported from Newsome creek, and miners from Elk City, Four Mile and other nearby camps are staking out claims in the snow. It is said that a porphyry dike, known to be 30 feet wide and carrying values to the amount of \$10 per ton, has been discovered by J. Wells of Asotin, who has opened the dike on three claims and the values are found to be uniform the entire width of the vein. Neither wall has been found and the exact width of the vein is unknown, but the development work shows the ore for 30 feet and the assays indicate the values to be evenly distributed the entire width. Mr. Wells has been prospecting for this lead for months, and before the vein was opened he was working in placer ground. It was here that he commenced to dig and in a short time he found the vein of porphyry. In appearance the ore is very similar to the Hogan dike, but the values are much more evenly distributed.

E. McIntosh has gone to inspect the McKinley mine, near Lucile, with a view to putting in a mill. He will be associated with P. P. Weher of Wardner in furnishing the mill for the mine.

It is reported that by May 1 the Hogan cyanide plant at Elk City will be operating. The plant will have a capacity of 400 tons a day. The Thunder Mountain G. M. Co., operating 8 miles from Idaho City, will put in a 100-ton cyanide plant this year.—M. J. Sweeney plans work on the Syndicate group, 11 miles east of Elk City. Five men are now working at the property.—The Elk City G. M. & M. Co. will purchase a 50-ton cyanide plant.

##### Kootenai County.

The Panhandle Smelting Co. is to build a silver-lead smelter on Lake Pend d'Oreille which may be running in May with an initial capacity of 200 tons a day. W. D. Casseday of Minneapolis, Minn., is president, F. W. Guilbert secretary and H. M. Williams of Spokane, Wash., manager. Smelter buildings, including a furnace building, ore bins with a capacity of 4000 tons, sampler building and ore docks, which run out 2200 feet into the lake, have been completed. The smelting company is developing the Venezuela group of four claims near Lakeview.

##### Latah County.

The Gold Bug M. Co. of Garfield, Wash., has changed the main office from Garfield, Wash., to Princeton, Idaho. The principal stockholders are W. Westacott, L. W. Carson, J. W. Cox, G. F. Stivers, B. Westacott, L. E. Trowbridge, W. Duling, W. J. Tipton, A. P. Johnson and Mrs. J. Drew. It is said that this company is making preparations to carry on mining operations on their claims in the Hoo Doo district.

##### Leimhi County.

(Special Correspondence).—R. L. Edwards says that the Kittie Burton M. Co. will put in a cyanide plant to cost \$250,000 on their mine at Salmon. A 30-stamp mill is running at the mine, but a large body of base ore having been found it is thought necessary to put in a plant of 300 tons capacity. Koehler & Keating have begun the construction of a concentrator at the Fourth of July mine, 30 miles from Salmon. The ore is a high-grade silver product. A rock crusher and rolls will be used instead of stamps and about twenty-five tons a day handled.

Salmon, Feb. 7.

##### Owyhee County.

The Traders G. M. Co. of West Superior, Wis., working ½ mile below Dewey, have driven the main tunnel 850 feet, and are employing eight men. C. L. Nichols of Silver City has charge. G. W. Roberts, president of the company, has been visiting the property.

##### Shoshone County.

In the mines in the Coeur d'Alene district many improvements are contemplated this year.

Reports from Mullan are to the effect that the Snowstorm mine is shipping between 80 and 100 tons of copper daily from the district. In addition to the shipments sent to Tacoma, small lots are sent to the Butte and Anaconda smelters.

The Morning and You Like mines at Mullan, owned by T. L. Greenough of Missoula and P. Larson of Helena, Mont., are equipped with modern appliances. The plants required to operate these two mines are strung out over 4 miles. The concentrating mill is 2 miles from the mine, connected by a narrow gauge railroad. It has a capacity of 800 tons of ore per day and makes a close saving of values. The low water during the year was a great drawback, the mill being operated by water power when available, but is provided with an auxiliary steam plant for seasons of low water. The power at the mine is air, compressed by water power over 4 miles distant and piped to the mine. Larson & Greenough first operated the Morning and You Like mines as lessees and purchased the two properties in 1898. From January, 1898, to January, 1905, the mines produced 1,270,796,054 pounds of refined lead and 4,085,918 ounces of silver. For the year 1904 they produced 29,884,076 pounds of refined lead and 507,853 ounces of silver, for which they received 3½ cents per pound for lead and 58 cents per ounce for silver.

With the exception of the Tiger-Poorman, every concentrator in the Coeur d'Alenes was closed down during

the cold snap. Slush ice has given the mills the most trouble. The Last Chance concentrator broke a shaft and it was closed down for repairs, but has resumed.—The Standard and Mammoth mills were both closed down for a time. The Mammoth resumed, but the Standard mill remains closed. The Bunker Hill concentrator also closed. The Morning and Hecla mills are closed.

The dry ore belt in the Coeur d'Alenes lies south of the South Fork, between Placer creek at Wallace and Big creek, says the Press of Wardner. It consists of three large parallel veins, and some think them identical with the lead-silver veins at Wardner on the west and the copper deposits on Stevens peak on the east. Some of the oldest locations in the district are on the dry ore belt, and some of them have extensive development, showing up large and well-defined veins having either a low value in silver or carrying small stringers of rich gray copper ore. These results have encouraged the prospector, but have not been sufficient to interest capital. One of the best known properties on the dry ore belt is the Argentine, 2½ miles east of Wallace. Much development has been done and in the early '90s considerable ore was shipped. The ore in the Argentine, like that in other properties on that belt, is largely spathic iron, with low values in silver. There is a demand for this ore at the smelters and they take it carrying as high as 35% iron and treat it free of charge.

##### Washington County.

The smelter of the Ladd Metals Co. at Landore is running successfully, and turning out fifteen tons of bullion daily.

#### MICHIGAN.

##### Houghton County.

Ten thousand pounds of dynamite stored underground in a magazine at the eighth level of No. 3 shaft of the North Kearsarge branch of the Osceola Con. mine exploded on the 8th inst., killing several men, three of whom have been accounted for, and injuring many others. The force of the explosion was felt for miles around, and men working in other portions of the mine some miles from the explosion were knocked down. The cause of the explosion is unknown, and may never be discovered, as W. Pollitt Jr., the man who had charge of the powder, was killed, no trace of him having been found. It is thought that four or five other men are still in the mine. The Osceola Con. Co. will suffer a heavy financial loss.

#### MISSOURI.

##### Jasper County.

(Special Correspondence).—G. Burgess and W. E. Morgan of Joplin have sold their mines at Block City, known as the Transfer M. Co., to N. T. Cadle of Chicago, Ill. One mill is in operation and ore was developed in several drill holes. These will be developed. Prospects for several new mills in that locality are good.—J. Roach of Joplin has a good prospect of zinc on the Granby land in Leadville hollow. The miners are drifting on a big face of ore. Mr. Roach is arranging to erect a mill on his Granby holdings in the spring.—L. N. Dana of Joplin, superintendent of the Glendale diggings, has begun the erection of a new 100-ton mill on a shaft 2 miles south of Joplin. The mill will be provided with electrical machinery and will be in operation by June.—S. E. Loy of Aurora has bought W. McCullah's interest in the No. 3 mine on the Boston-Aurora ground at Aurora, where a large body of high-grade zinc has been developed. The mine is owned by S. E. Loy and G. E. Maxwell, who are figuring on the erection of a plant at that place.

Joplin, Feb. 6.

##### Lawrence County.

(Special Correspondence).—Superintendent G. Stratton of the U. Z. and Federal land, at Aurora, is soon to let a contract for sinking a shaft to develop the body of zinc ore recently found on the Federal land.—Sinking on the Coleman Bros. shaft on the Rohrherson land at Aurora, to tap the body of jack recently cut by the drill, is progressing.

An electric power plant has been finished at Lowell, Kansas, which was built to furnish power to the zinc and lead mines in the Joplin district. The owners of the plant are Chicago, Ill., and Joplin capitalists. The company is known as the Spring River Power Co., with headquarters in Joplin. Over \$1,000,000 have been expended in two large dams across Spring river at Lowell, which will furnish the power to generate electricity. Fully a hundred mining plants around Joplin, Galena and Wehch City have signed contracts to take power of the new company and preparations are being made to install electrical machinery for this purpose.

Aurora, Feb. 7.

#### MONTANA.

##### Fergus County.

Superintendent H. H. Lang of the Kendall mine, near Lewiston, says the most important work being done is in the shaft which will go to the 1000-foot level. The work is going on raising from the 500-foot level. Mr. Lang expects to reach the surface in another month. The shaft will then be timbered and the hoist set. In one year the shaft will be in operation to the 800 level and will be pushed on to the 1000 level, as it is there that the new ore bodies were struck by the diamond drills a year ago. These deposits are new and are as rich as the old body, upon which the mill has been running ever since it was started. The old ore body still has a large amount of ore in sight. The company has ordered a large amount of machinery. Some of it, including the cable, is already on the ground. A 150 H. P. electric hoist, a compressor and large sinking and station pumps will arrive soon. The Kendall employs 100 men, and they are taking out about 300 tons of ore a day.

##### Jefferson County.

E. B. Howell is president of the Green Campbell M. Co., operating the Green Campbell mine at Iron Rod, in Silver Star district. It is one of the oldest gold mines in the Northwest. It carries enough silver and copper to pay operating expenses. It produced good ore a quarter of a century ago and has been operated with varying success since that time. The main shaft has been sunk 200

feet and large excavations have been made at intervals from the surface to the bottom of the shaft. The company now has 2½ feet of shipping ore and 9 feet of milling ore. Shipments are being made at short intervals with good results. A stamp mill is now on the ground and will soon be erected. The mine is drained to a certain extent by other mines which have been opened up lower down the mountain side. A recent shipment of twenty-six tons of ore netted \$2100. The Silver Star mining district is one of the oldest quartz mining camps in Montana. Gold is the chief product, with silver and copper as by-products. The district is largely operated by leasers.

#### Madison County.

The Watseca mine, at Rochester, has been closed down, the pumps pulled out and only watchmen remain. The large volume of water to handle and low grade of ore are said to be responsible.

Adjoining the Watseca, E. Hand, formerly connected with the Watseca, has arranged for resuming work on the Champion property. The mine is owned by Mr. Brice of Ohio and others. The Champion is an extension of the Watseca on the south. The shaft has been sunk to 180 feet and the mine is supplied with a hoist and other machinery; work will be begun at once to get the property in shape for mining.

#### Silver Bow County.

The total dividends paid by Butte mining companies up to Dec. 31, 1904, are:

Boston & Montana .....	\$38,525,000
Anaconda .....	24,450,000
Parrot .....	6,002,785
Montana Ore Purchasing .....	3,780,000
Butte & Boston .....	1,800,000
United Copper .....	730,000
Colorado (estimated) .....	7,000,000
Alice, Lexington, Britannia and other companies .....	4,000,000
Total .....	\$86,807,785

The Amalgamated, up to Dec. 31, has paid its shareholders \$24,812,127.

The Anaconda Co. is adding 200 feet to the shaft of the St. Lawrence mine and the Boston & Montana is sinking 200 feet on the West Colusa. When the work is finished the workings of the former will be 2200 feet deep and those of the latter 1600 feet. This will give both companies a vast area of stoping ground and enable them to run another year or two without being required to go deeper. There is plenty of ore in the upper workings of both mines, but it is the policy of both companies to keep the work of exploration well in advance of the stope and level work.

W. McAndrews and T. Greeley were killed in the Rarus mine at Butte through the breaking of the cable, falling from near the surface to the bottom of the shaft, the men being dropped into 300 feet of water. The cable was flat and 8 inches wide and was supposed to be perfectly safe. The accident occurred without the least warning. There had been nothing wrong with the cable as far as known. The cage had barely left the surface before the cable snapped, sending the two to their death. The only explanation that is offered for the breaking of the steel rope is that the cable, wet continually, was probably attacked by the cold to the extent that the steel could not stand even the slightest weight, and the frost, getting into the rope, finished the work of the water.

### NEVADA.

#### Esmeralda County.

(Special Correspondence).—Wall & Mott of San Francisco, Cal., have bought the Vista Grande mines, in Bullfrog district, 80 miles from Goldfield, from Stanley, Busch & Manning.—A. E. Humphrey and Carleton Bros. have bought 160 acres of property south of the Combination.

Goldfield, Jan. 6.

M. D. Draper, consulting engineer of the Conqueror M. Co. at Goldfield, reports that the ore body of the Tonopah Cluh claim occurs as an auriferous shale, associated with gypsum and porphyry between a silicified rhyolite and a hornblende andesite. H. Weber and M. Ish are interested in the company. —The Sherman Goldfield M. Co. has bought stock in the Goldfield Lucky Strike M. Co. and will start development on the Lucky Strike claim under superintendency of J. R. Davis. —At a meeting of the assayers of the Goldfield district it was decided that after Feb. 1 the following rates would go into effect, subject to discounts of 10%, 15% and 20% on monthly work amounting to \$50, \$75 and \$100 respectively: Gold, \$1.50; gold and silver, \$2; lead, \$1.50; copper, \$3; control assays, \$5; umpire assays, \$10. —E. A. Montgomery intends to build a mill at Beatty to treat ore from the Shoshone and surrounding claims. A new road has been cut through from Coyote holes to Beatty so that the trip can be made from Goldfield to Beatty in a day.

#### Lincoln County.

At El Dorado Canyon, in the southern end of the county, mines are being developed systematically. Heretofore they have been worked in a haphazard manner by "chloriders." The group of the El Dorado M. Co. is to be started up, says C. G. Austin, the principal owner.

The Quartette mine at Searchlight has started three batteries at work. Pending the arrival of the new and larger engine this is the greatest number of stamps that can be operated, says the Searchlight. On the 700-foot level the west drift is in 60 feet and the ore body is unchanged. To the east there is being exposed what will probably prove to be the largest ore body so far developed in the mine. A crosscut is being run to the foot, but as yet the wall has not been reached.

#### Lyon County.

H. E. Miller, one of the owners of the Bluestone and Douglas copper mines, in Yerington district, is making arrangements to ship several thousand tons of copper ore from the Douglas mine to Salt Lake City, Utah, for reduction. There is considerable ore on the dump and when this is shipped miners will be put to work breaking more ore. A rate of \$5 per ton for transportation between Wahuska and Salt Lake City has been made by the railroad company and the reduction charges will be about the same.

#### Nye County.

(Special Correspondence).—In the Reville mining district, on the east slope of South mountain, the Last Chance group is being opened by tunnels and shafts. A double-track tunnel, starting on the Last Chance mine, is to be run north through the Liberty and Black Eagle of the Independence group. The formation is porphyry and limestone, with belts of quartzite cutting through at irregular intervals. The ore occurs either in the limestone near porphyry or between the two formations. The outcrops vary from an iron ore carrying lead and silver to a quartz silver ore. The Reville mining district is 55 miles east of Tonopah and covers an area of 6 miles. The silver ores occur in pockets and isolated deposits in dolomitic limestone near dykes and cappings of quartz. It was discovered in 1866.

Tonopah, Feb. 7.

The Nevada legislature has passed a bill removing the county seat of Nye county from Belmont to Tonopah.

Recent developments in the Midway mine at Tonopah are said to have opened a vein 10 feet wide of good ore. This strike is on the 435-foot level. The values are chiefly in silver. R. Condon is superintendent. Shipments have commenced.

In a well ½ mile west of Goldreed, water has been struck at a depth of 18 feet, and the water quickly rose 8 feet. The water strike is as valuable as the finding of shipping ore.

#### Washoe County.

W. H. O'Brien, representing Eastern capitalists, has a \$10,000 bond on a half interest in the Three Thieves, Fiddling Kid and Bull Dog mining claims, in Peavine district, near Reno. Development will be continued.

### OREGON.

#### Douglas County.

The Continental mine, on South Myrtle creek, is running with a full crew. Superintendent W. B. Stewart reports that as soon as the season is advanced ore will be shipped to San Francisco. He also expects that machinery will be put in to reduce the low-grade ore early this year.

#### Grant County.

Manager W. W. Gibbs of the Copperopolis property states that he has completed the west crosscut, striking the body of copper ore at a point 120 feet from the place where it had been previously crosscut.

Reports from the Black Butte mine, in Fox valley, 20 miles from John Day, are that the mill is at work on the best ore yet uncovered. The ore is of good value, 90% free and so soft and friable that large quantities are run through the mill. It is said the company will bring water from the head of Beech and Fox creeks by a ditch 10 to 12 miles in length, with the probability of a good deal of fluming. The work will be undertaken the coming spring.

### SOUTH DAKOTA.

#### Lawrence County.

(Special Correspondence).—The Golden Reward smelter is to be blown in soon, and in anticipation the company's mines at Ruby Basin and elsewhere are being prepared for output. These mines comprise upward of 20 miles of workings. The smelter was closed down two years ago because of a disagreement with the union. The labor organization would not recede from the demands made and the smelter shut down. It is the only plant in the county which can successfully treat the refractory "blue ores" in the Cambrian and Carboniferous deposits. The Montezuma and Whizzers mines, at Deadwood, which supply iron flux to these works, are also being put in condition to resume production by Manager J. T. Gillmore. The smelter when in operation employs a large number of men.

Deadwood, Feb. 5.

The Deer Lick mine is on Deer creek, 10 miles west of Deadwood. The shaft is 40 feet deep and will be continued as a large working shaft several hundred feet. An air compressor, hoisting engine, boilers, blacksmith shop, etc., will be put in. J. E. Waddell is president, J. C. Mills vice-president, W. Reed secretary and treasurer, F. H. Nash general manager.

### UTAH.

#### Beaver County.

The zinc mill of the Horn Silver mine is ready for operation, reports W. H. Peck, manager of the plant. The plant was built to handle 300 tons a day. It will be put into service gradually, but will be brought up to the maximum as rapidly as conditions will permit. The mill will cost close to \$100,000.

#### Juab County.

The ore shipments from Tintic for the past week are given by the Eureka Reporter as follows:

Name of Mine.	Carloads.
Centennial-Eureka .....	48
Bullion-Beck .....	5
Gemini .....	16
Grand Central .....	6
Mammoth .....	2
Carissa .....	6
Lower Mammoth .....	2
Victor .....	1
Ajax .....	2
Tetro .....	4
Uncle Sam .....	2
Eagle & Blue Bell .....	6
Yankee Con. .....	7
Hopes .....	1
Eureka Hill .....	2
Uncle Sam mill (concentrates) .....	2
Total .....	112

#### Salt Lake County.

H. W. Horne, consulting engineer of the Boston & Terrace C. M. Co., developing a group of claims on the west side of the Great Salt Lake, in what is known as the New Foundland district, has returned from a trip to that property and says conditions are favorable there for the opening of a good producer. A tunnel is being driven to what is known as the Shepherd lode and which shows up well where developed nearer the surface. The tunnel is now in 280 feet. The mine is 8 miles from New Foundland station on the Lucin cut-off of the Southern Pacific.

It is reported that the smelting concerns operating in

the Salt Lake valley have concluded that the only feasible means of eliminating the fumes, of which there has been much complaint in the Salt Lake valley, is by the use of a copious supply of water. The Utah Con. M. Co. filed with the State Engineer a claim for 25 second feet of water to be taken from the Jordan river, near the smelter, and to be conducted by an 800-foot pipe line to the smelter for use in the regulation and control of the poisonous fumes. The gaseous laden waters will be conducted into the Great Salt Lake for final disposal there.

#### Summit County.

A new hoisting plant may be placed on the American Flag mine, near Park City, as the present machinery is inadequate. J. G. Rhoden is manager.—It is reported that the Daly-Judge mill at Park City will be started February 14. J. J. Daly is manager.

### WASHINGTON.

#### Snohomish County.

The Wayside M. Co., near Index, propose further development, says Superintendent Carter. Work is progressing toward the erection of a 3500 H. P. plant, their plan being to place a wing dam in the Stillaguamish river, near Rohe, and running a flume to Hubbard lake, using the lake as a reservoir for feeding the turbines. With the completion of the proposed three-compartment shaft from the fourth level to the surface above the railroad track, the gravity system of handling ore can be used. Ore may then be raised to the surface, 200 feet above the railroad level, and pass through the various processes of sorting and stamping, to the Monte Cristo cars, obviating the present system of shoveling.

#### Stevens County.

The Jay Gould mine, 3 miles east of Chewelah, which has been idle for several months, has started, with D. F. Strobeck of Spokane in charge.

The Enterprise at Chewelah, owned by the Enterprise M. & R. Co., has begun operations under Manager T. F. Hertzell. The main shaft will be sunk to the 200-foot level and ore will be shipped from the ore body recently opened up.

The bond on the Silver Queen mine, near Kettle Falls, is to be taken up and a company has been organized to develop the property. The principal men interested in the company are E. D. Olmstead, D. J. Bissel Jr., H. F. Case, A. H. Palmer, A. V. Bradrick, R. K. Green, H. M. Lee and W. W. Warner of Spokane. The property was bonded by R. K. Green last November and has been worked steadily since. A ledge 40 feet wide was uncovered on the surface, in which there was an 18-inch streak of pay ore. This pay streak widened as depth was attained and at 85 feet pay ore showed a breast of 35 feet.

### FOREIGN.

#### BRITISH COLUMBIA.

The Silver-Lead Miners' Association of British Columbia, at a meeting held recently at Nelson, decided to submit to the provincial government a request that the present tax of 2% on the smelter proceeds of ore mined in the province be changed to a tax of one-half of 1% on the gross value. It is estimated that the proposed law would have produced \$75,000 in taxes during the year, instead of \$66,000, produced under the operation of the 2% law. A. C. Garde resigned as president of the association and was succeeded by J. Cronin, manager of the St. Eugene mine at Moyie. Garde was formerly with the Payne mine. J. L. Retallack was made a special commissioner to go to Ottawa to urge upon the Dominion Government the importance of the zinc industry and to secure an investigation of its conditions in the province.

#### Ainsworth District.

The Marion mine, near New Denver, owned by the Maritime M. Co., is to resume operations under the direction of C. F. Caldwell of Kaslo, manager of the Maritime Co., but under the immediate supervision of T. St. C. Brindle and J. R. Thompson of New Denver. They expect to begin shipping in a short time.

#### Boundary District.

The Morrison mine, at Deadwood, has been taken over by the Montreal & Boston Con.—The Bay mine, at Greenwood, has been handed from F. K. Hall and H. V. Fuller for \$60,000 by San Francisco, Cal., parties.

#### Nelson District.

The May & Jennie mine on Forty-nine creek, 10 miles from Nelson, is being equipped with a 12-foot Hendryx cyanide agitator, capable of treating fifty tons a day. The mine is owned by the Reliance G. M. & M. Co., managed by A. H. Kelly. The mill will be running April 1. W. J. Elmdorf of Spokane made the plans.

#### Rossland District.

The oil concentration process introduced by the Le Roi No. 2 mine at Rossland in October, 1903, is reported to be financially unsatisfactory, and the Le Roi mill is now running on straight water concentration. The Le Roi No. 2 is making a profit of 50 cents a ton with water concentration alone, whereas there was a loss of \$1.03 a ton when the oil process was used. During a seven months' test run the oil process treated 4578 tons of Wilfley tailings, which averaged .107 ounce in gold, .227 ounce in silver and .394% copper, or a gross assay value of \$3.23 a ton. The final tailings after treatment with oil contained .076 ounce gold, .135 ounce silver and .076% copper, or \$2.10 a ton. That meant an extraction of \$1.13 a ton through the Elmore section of the mill. The total milling operations showed a loss of \$1.03 a ton. Oil at first cost 40 cents a gallon and the consumption was three gallons to the ton; later the cost was cut to 29 cents a gallon and the consumption to 1.3 gallon a ton. Even with these changes, however, the Le Roi No. 2 management decided that the system was not a commercial success, as extra fine crushing was required by the Elmore process. By water concentration the grade of the tailings on the Wilfley tables has been cut to \$2.20 a ton, and there is no room for the profitable operation of the oil system. The Rossland Power Co. of Trail at first planned to use the oil system, but finally cut it out. The White Bear mine at Rossland is trying the process.

The net smelter returns of the Le Roi No. 2 for the year ended Sept. 30, 1904, were \$371,000; the total expenses were \$245,000; the net profits were \$125,200. The average value of shipping ore was \$24.80 a ton, made up as follows: Gold, .909 ounce; silver, 1.426 ounce, and copper, 2.37%. The cost of producing shipping ore at the Le Roi No. 2 was \$4.22 a ton, including sorting, covering a production of 23,020 tons of shipping ore, 10,331 tons of milling ore and 17,151 tons of waste. By allowing for depreciation of plant, and adding the cost of development, which included 1556 feet of drifting, 135 feet of raise and winze, and 3617 feet of diamond drilling (the last costing \$2.22 a foot), the cost of production was brought up to \$6.28 a ton.

#### Vancouver Island.

Thos. Kiddio, manager of the Tyee C. Co. smelting works, at Ladysmith, will put in hot blasts in place of cold in smelting. At the present the ore is first roasted, then smelted, with the results that the matte is about 45% copper. Ordinarily, when ore is treated in the smelter, 12% to 15% is the result, requiring a second treatment to bring the matte up to the 45% standard. Hereafter most of the ore treated at the smelter will be by the hot blast, and roasting outside will be done away with.

#### MEXICO.

##### Chihuahua.

(Special Correspondence).—In spite of the recent increase in treatment charges for the siliceous ore of the Parral camp, the production continues to be fair. The total tonnage of ores shipped to the smelters for the month of January was 13,006 metric tons, locally treated by wet concentration and leaching plants, 15,437 metric tons, held for future delivery 24,214 metric tons, a total of 52,657 metric tons.—One of the most active producers is the San Francisco del Oro, producing 4000 metric tons of shipping ore per month, and of late the profits have been so large that the company, an English syndicate, contemplates to erect concentrating and leaching plants to handle their second ores which are at present held on the dump. Large reserves have been opened up and the underground development work pushed more than in any other mine in the district. There are three grades of ore shipped at present, a siliceous ore carrying high-grade silver values, a lead-silver ore and zinky-lead-silver ore, but all of them admit a fair margin.—The El Refugio mine has not been sold, as frequently stated during the last month. An option for \$1,500,000, Mexican currency, was lately held by the Guggenheim Exploration Co., but the examination of the company's experts disclosed only net in sight \$660,000, Mexican currency. The mine at present is producing from shipments to the smelters and the lixiviation plant about \$25,000 net per month from the ore reserves above the water level.

The Los Muertos mine has been bonded and leased to the house of Hillforth, who are sending ore from the eighth level to the Parral M. Co. This district offers a field for a process handling low-grade siliceous ores running 15 to 20 ounces silver. The hypophosphite and Russell processes have proven too expensive and give low extraction, the extraction cost being \$9 to \$10 Mexican per ton, with 80% extraction, not including a large silver loss in roasting.

Parral, Feb. 5.

##### Sonora.

The Wisconsin-Mexico M. Co., operating the Plomosa, Iris and Oh'Gee mines, near Huepac, 125 miles north of Hermosillo, on the Sonora river, is building a stamp mill under the direction of R. Graham. The company have a 30-ton smelter, briquetting machines, etc.

## Commercial Paragraphs.

In equipping its new English shops where the steel cars for the London underground railway are to be built, the American Car & Foundry Co. has purchased from the Ingersoll-Sergeant Drill Co. its entire pneumatic equipment, including air compressors and Haeseler hammers and drills.

THE annual convention of officers and branch managers of Crocker-Wheeler Co. took place at the main office and works, Ampere, N. J., Jan. 26, 27 and 28. Managers and representatives from all parts of the country were unanimous in predicting a prosperous season during the coming year in the field of alternating current generators and direct current generators and motors. On the evening of the 27th a banquet was held at the Cafe Martin in New York, at which the president of the company, Dr. Schuyler Skaats Wheeler, presided.

THE A. S. Cameron Steam Pump Works, foot of East 23rd St., New York City, report the sale of three more of their horizontal piston pumps to the O'Rourke Construction & Engineering Co., of New York City, contractors, for the improvement in the Pennsylvania R. R. tunnel, delivery being made to the Manhattan side. The above named construction company also have a number of Cameron pumps in use on the Weehawken side of the Pennsylvania tunnel, and along the line of the improvement in the New York Central R. R. tunnel in New York City.

A 250-TON copper smelting plant for the Saddle Mountain M. Co., Kolvin, Ariz., is being furnished by the S. H. Supply Co., Denver. This shipment includes a 36x140 copper matting furnace, No. 7 Connorsville blower, hollers, engines, pumps, 125-foot steel self-supporting stack, steel dust chambers, slag pots, etc. This company is also furnishing twenty 900-pound rapid-drop stamps to the Bertha Consolidated M. Co., Idaho Springs, Colo., with plates, power and crushers, to be added to the twenty stamps now dropping, doubling the capacity of the plant.

THE General Compressed Air Co., 3933 Olive street, St. Louis, Mo., found in the past that the gasoline engines and air compressors necessary for use in their

house cleaning machines were not satisfactory for their purpose and they proceeded to manufacture their own engines and compressors. Those have proven so successful that they will establish a separate department to exploit these machines for other purposes. Their air compressors are manufactured for electrical and gasoline power, and are direct connected. They are also made portable. Literature will be furnished on application to the company.

VISITORS at the St. Louis Exposition will probably remember a model of a concentrating plant in the Missouri exhibit at the Mines and Metallurgy building. This exhibit was erected by the American Concentrator Co., Joplin, Mo., and at the close of the Fair was sent to the Raleigh school of mines. It is stated that eight other universities in the United States, Canada and foreign countries are corresponding with the American Concentrator Co. with a view towards having them build model plants of the same character for use in their educational institutions. A similar plant to the one at the Fair is under construction for the University of Iowa. The value of such equipment to the universities which have mining courses is apparent, and it certainly speaks well for the product of the American Concentrator Co.

## Books Received.

"Report of the California State Debris Commissioner," W. W. Waggoner, gives a resume of work accomplished on the Yuba and Feather rivers for two years ending Nov. 1, 1904.

Professional Paper No. 35, of the United States Geological Survey is "The Geology of the Perry Basin in Southeastern Maine," by G. O. Smith and D. White. Its most important conclusion is that there are no coal deposits in the area.

"California Mines and Minerals," Bulletin No. 35, of the California State Mining Bureau, by C. G. Yale, gives a review of the mineral production of California for 1903, comparing with previous production and detailing county production. A valuable part of the publication is the maps of every county in the State, showing all towns and roads.

"Bi-Monthly Bulletin of the American Institute of Mining Engineers," No. 1, is the first copy of an innovation by which papers heretofore distributed separately in pamphlet form to members will be issued in a single volume every other month. Besides a summary of the proceedings of the eighty-seventh meeting, Lake Superior, September, 1904, the following papers are printed in full: "Application of Dry Air Blast to the Manufacture of Iron," by Jas. Gayley; "The Influence of Carbon, Phosphorus, Manganese and Sulphur on the Tensile Strength of Open Hearth Steel," by H. H. Campbell; "The Gold Mines of San Pedro, San Luis Potosi, Mexico," by G. A. Laird; "The Zinc Smelting Industry of the Middle West," by H. C. Meister; "The Fire Clays of Missouri," by H. H. Wheeler; "Decomposition and Formation of Zinc Sulphate by Heating and Roasting," by H. O. Hofman; "The Coal Fields of Missouri," by B. F. Bush.

## Trade Treatises.

The catalogue of the Carterville Foundry and Machine Works, Carterville, Mo., and the Galena Iron Works, Galena, Kansas, W. G. Bryant, proprietor, is descriptive of crushers, Cornish rolls, friction hoisters, pumps, pipes, jig grates and jig supplies.

The Westinghouse Machine Co. of East Pittsburgh, Pa., has issued a neat brochure on the Westinghouse-Parsons steam turbine. In addition to presenting typical illustrations of the turbine and the plants in which it is operating, the pamphlet gives a valuable account of the principles and development of steam turbines. It gives 284 typical tests of the turbine as a strong argument for its use. The subject matter is clearly presented, the illustrations are good and the appearance of the whole is attractive.

## Obituary.

G. J. BARRETT, superintendent of the Blue Bird mine, died at Granite, Grant county, Or., Jan. 31st, from pneumonia.

D. L. MILLER, formerly superintendent of the Sierra Queen mine, in Nevada county, Cal., died Jan. 31st at Nevada City from injuries received in a cave at the Oustomah mine.

GEORGE BAUER, a prominent banker and mine owner of Mancos, Colo., died at Guadalajara, Mexico, Feb. 1. Mr. Bauer was born at Siegen, Prussia, in 1848, came to America in 1865, and six years later went West to seek his fortune. After prospecting with varying success in nearly every known mining region of Colorado he settled in Mancos in 1881, engaging in mercantile business and banking. He was also interested in mining, and developed a number of good properties in the La Plata mountains. He developed the mines now owned by J. Doyle, and at the time of his death owned principal interests in the well-known Comstock mine on the La Plata river. Mr. Bauer was justly called the father of Montezuma county, he having probably done more for the development of that region than all others combined, and was known and respected over the entire State for his ability, charity and inflexible honesty.

## Personal.

ALFRED HARVEY is on professional business at Velardena, Mexico.

J. B. BROWN is superintendent of the Ranier M. Co. at Warren, Idaho.

B. THANE is superintendent of the Eagle River Co. at Eagle River, Alaska.

R. S. EDWARDS is manager of the Kittie Burton mine at Ulysses, Idaho.

K. H. MCLEOD of Silver City, Idaho, is spending the winter in New York City.

I. C. BOSS is building a stamp mill for the Combination mine at Goldfield, Nev.

A. J. McMILLAN has been re-elected manager of the Le Roi M. Co. at Rossland, B. C.

AUSTIN JACKSON is superintendent of the Rocco Homestake mine at Hamilton, Nev.

E. F. GORDON has been appointed superintendent of the Hillside M. & M. Co. at Dixie, Idaho.

V. G. HILLS of Cripple Creek, Colo., is examining mining property in Boulder county, Colo.

S. M. SMITH is manager of the Greyhound M. & M. Co. in the Senfoam district, near Boise, Idaho.

J. MORGAN has been appointed superintendent of the South Kalgurli mine at Kalgoorlie, West Australia.

G. E. KILEY has returned to Denver, Colo., from Prescott, Ariz., where he has been examining mines.

T. C. GRAY, manager of the Valley Queen mine, near Granite, Or., has been visiting in Spokane, Wash.

A. C. JESKEY has charge of the development work at the Golden Star mine, near Quincy, Plumas county, Cal.

M. D. KELLY has succeeded M. B. Kerr as superintendent of the Jumper mine at Stent, Tuolumne county, Cal.

P. DERMODY is superintendent of the Providence mine at Providence, in the Boundary district, British Columbia.

W. F. ENGLEBRIGHT of Nevada City, Cal., has resigned as hydraulic engineer of the South Yuba Water Co.

H. L. CHAMBERLAIN has been appointed superintendent of the Florence Iron River Co.'s mine in the Menominee range.

J. H. MACKENZIE of San Francisco, Cal., is at Tombstone, Ariz., recovering from his recent severe attack of pneumonia.

F. E. WITHEY is general manager of the Grand Traverse & Arizona M. Co. at Cave Creek, Maricopa county, Ariz.

T. R. GRIFFITH of Breckenridge, Colo., has taken the management of the Mainstay M. & M. Co.'s property at Keystone, S. D.

A. E. DRUCKER, formerly with the Roosevelt M. Co. at Ludlow, Cal., is in the Montezuma mining district, Sonora, Mexico.

G. F. BARNES has succeeded F. Kingsbury as general manager of the properties of the Crown King M. Co. at Crown King, Ariz.

G. E. BAILEY, E. M., is in San Francisco, Cal., from a trip of several months on the Mojave desert in California and southern Nevada.

W. W. BRADLEY of Berkeley, Cal., has gone to Bodie, Mono county, Cal., to take a position as night foreman of the mill of the Standard Con. M. Co.

M. H. JACOBS, consulting engineer of Spear's American Exchange, has returned from the King mine in Owyhee county, Idaho, to Boise, Idaho.

AT a recent meeting of the Hidden Fortune M. Co. at Deadwood, S. D., J. P. Allison was chosen president, G. D. Begole secretary, T. J. Steele general manager.

MANAGER WARREN BOGUE, Utah branch Mine & Smelter Supply Co., now occupies his new headquarters, 121, 123, 125 West Second South street, Salt Lake City, Utah.

E. A. TAYS has resigned as manager of the mines and smelters at Maconi, Queretaro, Mexico, to resume his practice as consulting engineer at Fuerte, Sinaloa, Mexico.

S. KEELING of Kaslo has been appointed assistant to Lead Inspector G. O. Buchanan at the Sullivan smelter at Marysville, in the Southeast Kootenay district, British Columbia.

J. T. MORROW, formerly superintendent of the Boston & Montana M. Co. and general manager of the Cananea mines in Mexico, is now manager of the Guaynopita Copper Co. of Guerrero, Chihuahua, Mexico.

C. D. ACKERS has resigned as superintendent of the Hidden Treasure and Mountain Gate mines at Bullion, Placer county, Cal., to accept a similar position with the Taber M. Co. at Gibsonville, Sierra county, Cal.

E. C. WOOD of Spokane, Wash., has resigned from the management of the Minnehaha and Hercules mines of Washington, to accept a position as consulting engineer of the Essex Con. Mines Co. at Angels Camp, Cal.

H. E. KIRK has been appointed first assistant superintendent of the Cananea Con. Copper Co. at Cananea, Sonora, Mexico, succeeding C. S. McHenry who has resigned. J. Duffin has been appointed second assistant superintendent.

## Latest Market Reports.

SAN FRANCISCO, February 10, 1905.

## METALS.

**SILVER.**—Per oz., Troy: London, 28½d (standard ounce; 925 fine); New York, bar silver, 61½c, refined (1000 fine); San Francisco, 61½c; Mexican dollars, 51c, San Francisco; 47½c, New York.

**COPPER.**—New York: Standard, \$15.50; Lake, 1 to 3 casks, \$15.50@15.50; Electrolytic, 1 to 3 casks, \$15.50; Casting, 1 to 3 casks, \$15.25. San Francisco: \$16.00. Mill copper plates, \$17.00; bars, 18@24c. London: £67 5s spot per ton.

The present outlook for copper during the present year is good, and in view of the probable increase in demand in the United States, due to increasing industrial activity, the output may be expected to be increased somewhat, but it is improbable that this increase in output will equal the increased demand. Should this prediction prove correct a still higher price than that at present quoted may be anticipated. Some statisticians who closely watch the market, and are familiar with all the important factors controlling the price, predict a decrease approximating 50,000 tons for export, which would undoubtedly force the price up in Europe, which will find a corresponding reflex in the United States.

**LEAD.**—New York, \$4.60; Salt Lake City, \$3.50; St. Louis, \$4.12½; San Francisco, \$4.60, carload lots; 4½c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5½c; pig, \$4.85. London: £12 17s 3d pig long ton.

**SPELTER.**—New York, \$6.20; St. Louis, \$6.30; London, £24 15s pig ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

**TIN.**—New York, pig, \$29.25@29.50; San Francisco, ton lots, 30c; 500 lbs., 30½c; 200 lbs., 30½c; less, 31c; bar tin, 32½@35c. London, £131 5s spot.

**PLATINUM.**—San Francisco, crude, \$18.50 per oz.; New York, ingot, \$19.50 per Troy oz. Platinum ware, 75@82c per gram.

**QUICKSILVER.**—New York, \$40.00@41.00, large lots; London, £7 12s 6d; San Francisco, local, \$38.00 per flask of 75 lbs.; Denver, \$45.00.

**BABBITT METAL.**—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 31½c; Eclipse, 35c. **SOLDER.**—Half-and-half, 100-lb. lots, 19.50c; San Francisco, Plumbers', 100-lb. lots, 16.25c.

**ZINC.**—Metallic, chemically pure, 50c; dust, 7½c, 10c; sulphate, 7½c, 10c.

**NICKEL.**—New York, 55@60c per lb.; ton lots, 40@47c.

**ALUMINUM.**—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31@34c.

**ALUMINUM.**—No. 1, 99%, small lots, 37c per lb.; 100 lbs., 35c; 1000 lbs., 34c; ton lots and over, 33c, Pittsburgh. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburgh.

## STRUCTURAL MATERIALS.

**IRON.**—Pittsburg, Bessemer pig, \$16.85@17.10; gray forge, \$16.85; San Francisco, bar, 3c per lb., 3½c in small quantities.

**STEEL.**—Bessemer billets, Pittsburgh, \$25.00@26.00; open hearth billets, \$25.00@26.00; San Francisco, bar, 7c to 12c per lb.

**WHITE LEAD.**—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, ½c per lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

**LUMBER.**—(Retail): Pine, ordinary sizes, \$24.00@25.00; extra sizes higher; redwood, \$28.00@30.00; latb, 4

feet, \$4.50@5.00; pickets, \$21.00; shingles, \$2.50 for No. 1 and \$2.25 for No. 2; shakes, \$13.50 for split and \$15.00 for sawed; rustic, \$28.00@35.00.

**NAILS.**—This week the basic prices are: Wire, \$2.77; Cut, \$3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, \$3.35; Cut, \$3.55; 10d to 16d, Wire, \$3.45; Cut, \$3.35; 8d, Wire, \$3.50; Cut, \$3.50; 6d and 7d, Wire, \$3.60; Cut, \$3.60; 4d and 5d, Wire, \$3.70; Cut, \$3.70; 3d, Wire, \$3.85; Cut, \$3.85; 2d, Wire, \$4.10; Cut, \$4.10. Special rates for carload lots.

**LIME.**—Santa Cruz, \$1.25 country, \$1.25 city per bbl.

**CEMENT.**—Imported, \$2.15@2.65 per bbl.; California, carload lots, \$2.10 f. o. b. at works; small lots, \$2.40 per bbl. in sacks, 4 sacks to bbl., 10c for each sack returned.

## GENERAL SUPPLIES.

**ANTIMONY.**—New York, Cookson's, 8½c; Hallett's, 8½c; San Francisco, 1000-lb. lots, 9c; 300@500-lb. 9½c; 100-lb. lots, 10½c.

**COAL.**—San Francisco, coast, yard prices: Wellington, \$8.00; Seattle, \$6.50; Coos Bay, \$5.50; Southfield, \$8.00. Cargo lot, Eastern and foreign: Wallsend, \$7.50; Brymbo, \$7.50; Pennsylvania, hd., \$14.00; Scotch, \$8.00; Cumberland, \$13.00; Cannel, \$8.50; Welsh Anthracite, \$13.00; Rock Springs, \$8.50, long ton: Colorado Anthracite, \$14.00. Coke, \$10.50 per ton in bulk, \$13.00 in sacks; Sunnyside, \$8.50, long ton.

**POWDER.**—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1\*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1\*\*, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2\*\*, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2.00 per keg.

**CAPS.**—3x, \$5.50@6 per 1000; 4x, \$6.50@7; 5x, \$8@8.50; Lion, \$9@9.50, in lots not less than 1000.

**FUSE.**—Triple tape, \$4.00 per 1000 feet; double tape, \$3.50; single tape, \$3.10; Hemp, \$2.75; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 and up.

**CANDLES.**—Granite 6s, 16 oz., 40s., 11c per set; 14 oz., 40s., 9½c.

**CHEMICALS.**—Cyanide of potassium, 98%-99%, jobbing, 23@24c per lb.; carloads, 23@24½c; in tins, 30c; soda ash, \$2.00 per 100 lbs.; bysulfate of soda, 3@3½c per lb.; caustic soda, in drums, 3@3½c per lb.; Cal. s. soda, bbls., \$1.10@1.20 per 100 lbs.; sks., 90c@1.00; chlorate of potash, 12@13c; nitrate of potash, 6½@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2½@2¾c; flour sulphur, French, 2½@—c; alum, \$2.00@2.25; California refined, 1½@2c; sulphide of iron, 8c per lb.; copper sulphate, 5½@5¾c; chloride of lime, spot, \$2.50@2.75; sulphuric acid, in carboys, 66% B, 1½@2c per lb.; nitric acid, carboys, 8c per lb.

**BORAX.**—Concentrated, 6@7c per lb.; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

**BONE ASH.**—Extra No. 1, 5@6c per lb.; No. 1, 4@5c.

**LITHARGE.**—Pure, in 25-lb. bags, 8@9c per lb.

**MOLYBDENUM.**—Best, \$2.75 per lb.

**CHROMIUM.**—90% and over, 80c.

**PHOSPHORUS.**—American, 70c.

**SILVER.**—Chloride, 90c, 90c@1.00; nitrate, 55c.

**RED LEAD.**—500 lbs. and over at one purchase, 7½c; less than 500 lbs., 7c.

**MAGNESIUM.**—Pure, N. Y., \$1.60.

**MANGANESE.**—Per lb., \$2.75.

**SODIUM.**—Metal, 50c.

**BISMUTH.**—Subnitrate, 2½c.

**URANIUM.**—Oxide, 7½c, \$3.50.

**MERCURY.**—Bicbloride, 7½c, \$1.25.

**TUNGSTEN.**—Best, 7½c, \$1.25.

**FIRE BRICK.**—Domestic, carloads 1000, f. o. b., factory square, \$25.00; soap and split, \$22.50; arch and wedge, \$27.50; skew back, \$30.00; circle, \$32.00.

**FIRE CLAY.**—Domestic, 1 ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, \$8.50.

## New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market Street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING JANUARY 31, 1905.

781,123.—NEWSPAPER WRAPPING MACHINE—J. L. Boyle, Harrisburg, Or.  
781,181.—TELEPHONE MOUTHPIECE—W. K. Brackett, Alameda, Cal.  
781,591.—RAZOR STROP—J. S. Burk, Prosser, Wash.  
781,331.—OIL BURNER—J. H. Davis, Oakland, Cal.  
781,501.—DOOR SECURER—W. P. Dohson, Grants Pass, Or.  
781,085.—LOCK—A. O. Fossum, Tacoma, Wash.  
781,284.—OIL BURNER—S. T. Johnson, Vallejo, Cal.  
781,534.—JAR COVER—J. A. Landsberger, Alameda, Cal.  
781,614.—CONVEYER—W. L. McCahe, Seattle, Wash.  
781,543.—STREET CLEANER—D. G. McClay, Santa Ana, Cal.  
781,093.—HYDRAULIC WEIR—W. S. Post, Los Angeles, Cal.  
781,361.—DOOR CLOSER—O. Rice, Oakland, Cal.  
781,085.—LOGGING APPARATUS—H. E. Robertson, Portland, Or.  
781,096.—LOGGING APPARATUS—H. E. Robertson, Portland, Or.  
781,369.—HAT HOLDER—W. L. Scott, San Francisco.  
781,240.—RENDERING OILS LIMPID—E. A. Starke, Alameda, Cal.  
781,242.—MANUFACTURE OF GAS—J. C. H. Stut, Oakland, Cal.  
781,380.—MANUFACTURE OF GAS—J. C. H. Stut, Oakland, Cal.  
781,243.—FOLDABLE TRUCK—S. Thompson, Eureka, Cal.  
781,477.—HATCH COVER—T. Walker, Portland, Or.  
781,528.—CAR BRAKE—H. H. Warner, Tacoma, Wash.  
781,253.—KNITTING MACHINE—C. D. Whitcomb, Glendora, Cal.  
781,255.—FIRE BRICK—F. A. Widdows, Stockton, Cal.  
781,262.—VEHICLE WHEEL—Z. Wevers, Santa Cruz, Cal.

## Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

**METHOD OF RENDERING ASPHALTIC OILS MORE LIMPID.**—No. 781,240. Jan. 31, 1905. E. A. Starke, Alameda, Cal. This invention relates to a method for reducing the viscosity of heavy crude oils and particularly oils of asphaltum base. The object of the invention is to so treat the heavier asphaltic oil that, while retaining all its original constituents, it will be rendered permanently limpid, and thus in condition to be transported through pipe lines, etc. It consists in a process and apparatus adapted to bring about the desired result.

**OIL BURNER.**—No. 781,331. Jan. 31, 1905. J. H. Davis, Oakland, Cal. This invention relates to improvements in liquid and gaseous fuel burners designed for use particularly in stoves and grates. Its object is to provide a cheap, simple and practical burner for heavy oils which may be applied to stoves or furnaces already in use, which is not apt to carbonize, which will permit a regulation of the amount of heat, and which will produce a steady, broad and smokeless flame. It consists of necessary construction and combination of parts adapted to bring about the desired result.

**TOILET AND HAT HOLDING APPLIANCE.**—No. 781,369. Jan. 31, 1905. W. L. Scott, San Francisco, Cal. The object of this invention is to provide a device or appliance which is especially convenient for travelers, those visiting theaters and like places of public gathering, and for such purposes as it may be conveniently adapted for. It consists of a support, a hook carried upon one end, a hinge member upon the opposite end, a segmental yoke having its segmental portion forming the other member of a hinge, said yoke being substantially semi-circular in form and having interturned ends, a rim having holes diametrically opposite with which the ends of the yoke engage and form a pivot about which the rim is turnable, a mirror carried upon one side of the rim and a convex cushion carried upon the other side, and other details of construction.

**FOLDABLE TRUCK.**—No. 781,243. Jan. 31, 1905. S. Thompson, Eureka, Cal. The object of this invention is to provide a light, handy, compact, durable, practical truck for the use of expressmen and others in the easy handling of trunks, boxes and like bulky packages, and which truck can be folded into small compass and stowed into a wagon, and which also can easily be run over carpets or polished floors without danger of injury to the latter.

## FOR SALE.

We have a Developed Gold Mine,  
Patented, Near the Sheep Ranch Gold Mine,  
Calaveras County, California,  
With \$25,000 worth of ore blocked out.  
Will give a long working bond on same.  
Goldfield and Tonopah claims for sale.  
SIERRA NEVADA DEVELOPMENT COMPANY,  
919-914 Mutual Savings Bank Building, San Francisco, Cal. John D. Hoff, M. E., Manager.

## BUSINESS OPPORTUNITIES

FOR LEASE.  
A Gold Mine

which has produced \$500,000. Equipped with Ten-Stamp Mill and Concentrator, and in running order with Boilers and Engine. Electric Power if desired. Free Milling and Concentrating. Estimated ore blocked out, \$100,000. Address "Mine," care of Mining and Scientific Press.

"THE OLD WAY."

The mortar shown as "The Old Way" conveys the idea of why the die cups, the stamps break so often, and the hack screens prove so unsatisfactory, besides the annoyance of keeping the hack chute clear.

In the Moyle Mill the ore drops over a circular chute and is kept in motion by the stamp itself as well as by gravity. Then the ore feeds evenly on die, thereby lessening the cup of die, less breaking of stamps, and satisfactorily using screens all around. Greater capacity. Easy to operate. This is one feature, and there are many to the Moyle Mill.

## Seeking a Mining Method.

Not infrequently the mine superintendent casts about for a method by which he can extract a given body of ore at the least expense. In most cases the most economical method is the result of improvement from time to time on the various methods tried. The main consideration is economy, but this is not the only important matter to consider in deciding upon a mining method applicable to some unusual condition. The chief consideration, it is admitted, is usually expense, and this it is desirable to reduce to the lowest possible point compatible with other considerations, mainly the safety of the men and the recovery of all the ore. As few ore bodies can be mined without more or less preliminary and preparatory expense, it is desirable to extract as large an amount of the ore in the vein as possible. The factors which cause unusual expense are very hard or very soft ground; bad walls; abundance of water below a natural drainage level; scarcity of timbers; the low dip of the vein—too low for the rock to "run" when broken in the mine; difficulty of approach to the ore body, owing to rugged topography of the country; high wages. Each of these is a factor in increased expense over a normal condition, and some mines have several of them to contend with. No rule can be laid down as the best to follow, for each case must be treated in accordance with the existing conditions. Where a large vein has a low dip— $20^{\circ}$  to  $30^{\circ}$ —it may be advisable to open the mine through the medium of an inclined shaft sunk in the foot wall of the vein, in

preference to a crosscut tunnel driven in on the level. When such a tunnel strikes the vein the facilities may be as good as it is possible to make them, and these conditions may be taken advantage of for a distance of 200 or 300 feet back toward the mouth of the tunnel, but farther than that the raises necessary to connect the crosscut with the vein, and the methods of handling the ore in the stope, become disad-

vantageous, and the tunnel then is the cause of increased rather than diminished expense. Where the mine is opened through an incline sunk on the foot wall of the vein, or in the foot wall country rock, which latter in many instances is preferable, as it admits the construction of ore pockets under the level, and every portion of the vein is accessible throughout the entire depth of the shaft, to the extent of its relation to the shaft on the strike of the vein. The cutting out of ore pockets will greatly reduce the expense of handling ore, as all that is broken above the level may be trammed to the station and dumped, where it can be loaded into the skip from chutes at minimum cost. The shaft, being in the country rock under the vein, is permanently located, and, to avoid the effect of heavy blasting in the stopes above, it is advisable to place the shaft at least 20 feet lower than the vein. The ore pockets reach from the foot wall of the vein to the back of the shaft, having the vertical side facing the dip of the vein. Skips lowered beneath the chute door may then be readily filled, no matter how flat the vein above. If filling is required, as it must be, unless the vein is worked by room and pillar method, a winze should be sunk in the hanging wall country from the surface. The filling may then be obtained on the surface from open cuts, by the mill hole method, provision being made to drain away any water falling or running into the open excavations. This rock shaft need not be placed directly above the working shaft, but at some distance away on either side. These preliminary arrangements completed, mining may proceed at various levels, the amount of timber used being determined by the standing qualities of the walls and the ore itself. Proceeding thus, all the ore should be recovered.

## Trials of the Millman.

The pathway of the millman is not always strewn with roses, nor with appreciation of his efforts. There are often instances when the mill foreman is aware that the saving being made under his supervision is considerably below what it should be, though as close as can be accomplished with the means at hand. It is no new thing to see a mill built in what the designer styles modern, up-to-date fashion, but when the practical millman takes charge of this mill and endeavors to do good work he finds himself unable to do that which he knows should be done. The ore may be of such a character that it is impossible to make a high saving without special apparatus, and this the mill does not possess, and while the necessary addition could readily be made, the owner does not consider it necessary, and either refuses or neglects to provide it. The millman has to contend with roughly taken headings samples, which may run high or low, as the case may be, for him and hopper samples vary greatly in a mine where the values are not evenly distributed. If the mill output exceeds the call of the headings samples, well and good; but if it falls below the amount called for by these head samples, taken from cars, bins and hoppers, there is trouble for the millman. Take the instance of a large operating mine. The ore consists of quartz, schist, slate, talc, veins of hard mineral and zones of soft, with more or less crushed and talcy gouge. The values cover a wide range, from a dollar or two per ton to specimen rock; sometimes there is a high percentage of free gold, at other times the values are largely in the sulphides. Here head samples necessarily must vary. So, too, will the samples taken below the plates, and also below the concentrators, unless proper means be supplied to treat the ore. The water supply and power arrangement may be defective and not constant, which must have a direct influence on amalgamation and concentration. Under such conditions the millman should be selected for his known experience and then given carte blanche to make any necessary changes in the mill that his experience suggests.

When such conditions as above outlined are found—and such actually exist, both in mine and mill—the battery must have a constant supply of water, under a fixed head, or good work can not be done either in amalgamation or on the concentrators. The crushing of the ore will result in the creation of a relatively small amount of comparatively coarse sand, depending on the screen and height of discharge, and a large percentage of slimes, and this applies to sulphides as well as gangue minerals. Close concentration of such material is impossible without classifiers, which will send coarse material to one machine and slimes to another. An absolutely unvariable speed of machines, as well as even water supply, is indispensable to good work, for when the machines are adjusted to slow speed, say, 160 revolutions per minute—a speed generally too slow—and fairly good work is being done, and then the machines speed up to 200 revolutions, because of increased water pressure at the wheel; the sand will be carried over with the sulphides and dirty, low-grade concentrates result. If adjusted to 200 revolutions and the motive power is disturbed, so that the machines slow up, high-grade concentrates may result, but high-grade tailings also. Therefore, it is imperative that such arrangements be made as will insure a uniform speed of the machines and a uniform supply of fresh water, distributed from a tank where the pressure will be constant. The machines should be always run by a special wheel; but it is not enough to provide this if the water pressure can not be kept constant. So important is it that the concentrating machines be run at uniform speed that some millmen devise ingenious methods of equalizing their speed by the use of cone pulleys and other devices, with large dials or other indicators which at once attract attention if the machines run either too fast or too slow.

FOR months past the oil producers of the State of Kansas have been at war with the Standard Oil Co. and the transportation companies over the handling of the oil output in that State. The climax has apparently been reached by the passage of a bill by the Legislature of Kansas appropriating \$410,000 to build a refinery in which to treat the oil output of that State, the labor to be performed by convicts.

Action taken by the Oil Producers' Association of Kansas has resulted in the introduction of a resolution in the House of Representatives requiring that the Secretary of Commerce and Labor investigate the causes of the low price of crude petroleum, particularly in the State of Kansas, and to inquire into the reason for the great difference in the price of the crude oil and the refined product. If the Kansas oil producers gain their point, it will probably have the effect of inducing the oil producers of other States to attempt to do likewise.

## Gold From the Sea.

At Bryon hay, New South Wales, Australia, the most extensive and costly plant ever built to operate the old-time "fake"—that of extracting gold from sea water—has lately been completed. As described by the Town and Country Journal, it comprises a basin connected with the sea and having a capacity of 40,000 gallons. It is supplied with a high-tide inlet pipe and a low-tide outlet pipe, each provided with a valve. At high tide the gold-bearing water is allowed to run into the tank where the operation of ostensibly extracting the gold is gone through, and at low tide the non-auriferous tailings water is allowed to escape into the ocean again. It is calculated to treat 18,000 gallons per day, and an extraction of  $\frac{1}{2}$  grain, or about 2 cents per ton, it is claimed, will yield a profit. The cost of this outfit thus far is said to have been nearly \$15,000. It is the intention to cover the bottom and sides of the tank with canvas. After a tank of water has been discharged there remains on the floor and sides of the tank a coating of sediment, which will be pumped up to a tank and the cyanide process in some form applied and the gold recovered. All the power required about the plant is furnished by the waves, and, as the operations are largely automatic, the expense will be very low. As the sea water is supposed to contain from 5 to 10 cents per ton, the manipulators can figure a handsome profit on paper. This old-time swindle has been operated in various parts of the world in all sorts of guises at intervals for many years past. Many devices calculated to impose on the ignorance of the public generally have been devised, such as evaporation of the water and separation of gold from the mineral salts, electro-plating the gold on copper plates suspended in the water, precipitation of the gold by ferrous sulphate and other equally visionary schemes, which would be likely to appeal to the credulity of those seeking investment; but this last effort surpasses in boldness and magnitude anything yet attempted in this direction. It is strange that the proposition has been permitted to advance so far in a country where the mineral production is under such strict Government control.

THE metal miners of the Rocky Mountain and Pacific Coast States usually build substantially and well, but it is not always necessary to go to great expense, in construction, particularly such as is often seen in the West. Prospectors build cheaply, usually, proving that elaborate works are not always required, but with working mines it is generally considered that a frail appearing structure is contrary to the best interests and needs of the property. In the zinc-lead districts of Missouri, there are scores of mines equipped with frail-looking head frames, of what in the West would be considered unique design, but these frames are found to answer every purpose, are inexpensive, and made of lumber in which the largest pieces are not above 8x2 inches. They are easy of construction and require no particular architectural or engineering skill, and are not built on scientific lines, but they cost little and do the business—and this is the main thing after all.

THE attempt to secure the passage of an eight-hour bill affecting miners, mill and smelter men in Colorado has met with strong opposition and will probably be amended, if passed at all, so as to not materially affect miners and metallurgical workers. The experience of the past year has not been forgotten, nor is it likely to soon be. All engaged in the mining industry in that State are earnestly hoping for continued peace and prosperity, and this sentiment is clearly reflected in the acts of the Legislature.

THE average young American mining engineer usually has a desire to leave his native country, to go into distant lands, where he may be a pioneer, and distinguish himself by overcoming great difficulties, earning fame and fortune. The idea is suggested, no doubt, by the success of a number of American engineers who went abroad and earned the much sought after fame and fortune; but the greater number of these men—all, in fact, who have made great success—had previously distinguished themselves at home, where there were difficulties, both mechanical and metallurgical, to overcome, and who had already learned their lessons in the hard school of experience after leaving the university. There are the same opportunities existing to-day—mines in situations remote from railroads and where conveniences are few, where special mining methods must be applied and metallurgical experiments made. Despite the advanced stage of knowledge of mining and metallurgical science, mistakes appear to be of as frequent occurrence to-day as ever they were in the past. There is no need of a young American engineer going to Africa, to China, to the deserts of Australia, or to the towering mountains of South America, so long as so much remains to be done in the United States. There are important questions to be solved in the economy of mining and metallurgy in every Western mining State—new districts to develop, new methods to discover and apply. The problem of smelter fumes is in itself a matter to engage careful attention. The fumes can be allayed in most instances by well-known processes, but to accomplish this without increasing the expense of smelting, and to find a market for the several by-products of these extraordinary operations, is something to ponder over. In some districts metallurgical methods which will cheaply extract sufficient values from complex ores to afford a profit are greatly desired. There remain and are constantly occurring unsolved problems everywhere, and to these the young engineers should give their attention.

## CONCENTRATES.

COPPER silicate when roasted with sulphide of iron results in the formation of copper sulphide and iron silicate. When heated with metallic iron, silicate of iron and metallic copper result.

FLOODED mine workings may sometimes be tapped with safety from adjoining workings by means of bore holes, though there is always an element of extreme danger present, particularly when the column of water is high.

WHILE the mining law may be construed liberally, and the courts usually favor the bona fide locator, there is no disposition on the part of the courts to shield a locator who neglects to perform his assessment work as required by law.

SULPHURIC ACID may be made from the roasting of sulphide ores and the copper leached from the roasted sulphide copper ores by means of dilute solutions of sulphuric acid, but this process is complicated and involves many chemical reactions. The process may be applicable in some such manner as suggested, but that it would prove commercially successful is less certain.

WHERE an association or company locates 160 acres of placer ground in one claim, as provided by law, only \$500 worth of work or improvements is required to proceed to patent, and this labor or improvements may be made at the option of the claim holders, within a week, or may extend over a period of five years, until the necessary work has been accomplished as annual assessment work.

ANTIMONIAL ores carrying gold and silver are difficult to treat, for the reason that roasting is usually required, and the fact that antimony fuses at a comparatively low temperature renders this difficult. Successful roasting of antimonial ores can be accomplished by treating the ore several times at moderate heat between 400° and 700° F. This gradually volatilizes the antimony and sulphur and the ore is finally brought to a proper condition for further treatment, by either wet or dry process.

THE best way to test rock supposed to contain gold is to pulverize it in a mortar, first thoroughly cleansing the mortar and pestle to avoid being "salted" by rich rock which may previously have been crushed in it. If the ore contains sulphurets, crush and concentrate in a pan or hornspoon, dry and roast to a red heat to burn out sulphur. No need to use salt in roasting. Grind in a mortar and pan as with quartz. As with the latter, if no gold is obtained on carefully washing, have the ore tested by reputable assayer.

WHEN it becomes necessary to place timbers in a shaft lined with masonry, to carry guides, ladders, etc., the ends of the main timbers may be set in the masonry; but in time they will rot, and the work of replacing them will be more expensive than if the square-set method of placing and wedging the timbers he employed. The engineer in charge of this work should be able to judge from conditions in neighboring mines of the probable life of timbers under such conditions and the economics of the situation studied out.

IN constructing gravity tramways it is customary, where possible, to give the upper end of the line a heavier grade than the lower portion in order that the loaded car may start the empty one up more easily. Such tramways are usually run on a brake, or the cars descending would get beyond control. In some instances ore is sent from a dump above a mill to the mill through a steel pipe 15 to 20 inches in diameter. Provision must be made at the lower end to receive the ore and prevent it doing damage to the mill. It is best to keep a chute of this description filled at the lower end.

WHERE it is necessary to change the angle of dip of a shaft, whether from vertical to inclined or from one degree of inclination to another, the curve should be of sufficient radius to avoid "shock," when the skip or cage reaches the curve, or the vehicle may leave the track—particularly where fast running is the rule. Where conditions are such that the change cannot be properly made, it is better to put in a guide to keep the wheels from leaving the track. Angle iron is useful for this purpose. The guide rail is turned up slightly at its upper and lower ends, to prevent the wheels from striking upon entering the space between the main rail and the guide rail.

WHERE the location of a quartz claim takes more than 1500 feet on the vein or lode—the amount permitted by the statutes—whether the excess be at one end of the claim or at both ends, a subsequent adjoining locator may place the stakes of his claim at the distance from the senior locator's discovery shaft claimed by the latter on his location notice. Thus, if A claims 500 feet north from his location stake and 1000 feet south from the same stake, he can take no more than the distance

stated, and should he place his north end stakes 600 feet from the discovery stake (claiming but 500), B may come to within 500 feet of A's discovery stake and locate his south end line.

THE copper of the world results from four sources: Native copper, produced chiefly by the mines of the Lake Superior region; from sulphide ore by smelting in blast and reverberatory furnaces; by the smelting of oxidized ores in blast furnaces, and by the leaching of the metal from natural and artificially oxidized ores by one of several processes. The largest leaching operations are carried on in countries where labor is comparatively inexpensive, but the same methods are applicable to similar ores everywhere. The ores treated by the leaching method are uniformly low grade, it being more economical to smelt the higher grade ores, whether oxidized ores or sulphides.

WHEN high-grade values, in the form of slimes, are carried over the tail end of the concentrating machines the problem of saving them becomes difficult, as it involves the necessity of separating the solid from the fluid portion of the tailings. At some works this is attempted by running the tailings over canvas plants, and sending the final water to settling tanks where the rich slimes again appear floating on the surface. The overflow from these tanks is then conducted through a pipe and discharged into another tank under water, when the microscopic particles now completely submerged settle to the bottom, unless the current be so strong that they are brought to the surface again by the agitation. This may be guarded against by making the lower settling tank sufficiently large to prevent it.

WHAT is known as the longwall method of mining coal is seldom applied to metal mines, though there are probably numerous cases where this method might be applied to advantage. By its employment the entire contents of a flat vein, not too thick, may usually be safely mined. Its success depends upon the caving of the roof a few feet back of the working face. The roof of coal seams is well adapted to this method in many places, but not so the hanging wall of metalliferous veins. In the latter the hanging wall usually stands very well or very poorly, and in the former case, if unsupported, often eventually falls when not expected and causes fatalities which might have been avoided. The caving of large masses of rock, even in stopes which have been abandoned, should be prevented if possible, as the concussion may result in disaster in other workings connected with the caved stope. Where timbers can not be afforded, it is often better to work by the pillar and room method, by means of which from two-thirds to three-fourths of the ore may be safely recovered. After this method has been safely employed, an attempt is often made to rob the pillars, and sometimes this is attended with disastrous results.

A WIRE hoisting rope is not equivalent to a solid bar of iron or steel of the same size. About one-quarter of the sectional area is occupied by voids and three-fourths by the solid metal. Plough-steel wire, from which the best hoisting ropes are made, is estimated to have a breaking strength of from 190,000 to 300,000 pounds per square inch. In determining the breaking strain of a hoisting rope the manufacturers do not usually claim more than 60% of this ultimate tensile strength and place the safe working load at about one-fifth to one-sixth that of this assumed safe breaking strain. Thus a hoisting rope of 1 inch diameter should not break under a strain of less than 140,000 pounds—the manufacturers place it usually at 88,000 pounds (forty-four tons), and fix the safe working load at 8.8 tons. This is necessary owing to the extraordinary strains due to sudden starting of the load, or the sudden stopping when the load is in motion. In such cases the strain is sometimes from eight to ten times that of the load. A rope is always at its best when new and from the beginning of its use it commences to deteriorate. Ropes in wet mines deteriorate much more rapidly than in those which are dry, as the moisture is constantly present within the core of the rope and the tendency to rust is thereby increased, particularly on the end of the rope next the skip or cage. For this reason hoisting ropes should be thoroughly and frequently lubricated with a proper grease or oily substance which should be put on hot so that it may penetrate to the center and protect every portion of the rope, within as well as without. Crude petroleum is used at some mines with satisfactory results. It is easy of application and lasts well if the oil is not too light. In mines where the water is charged with acid, as in many copper mines, even greater care must be exercised than elsewhere.

A PLACER LOCATION made by an association of eight persons may include 160 acres, or any less number, and such location (say 160 acres) constitutes one claim. The Federal statutes require that the individual locator of a 20-acre tract must perform \$100 worth of work on his claim annually, but a location made by an association of individuals embracing more than twenty acres may undoubtedly be held by performing the same amount of labor on it as is required on the 20-acre claim of a single individual. There is an important distinction, however, between an association claim of 160 acres taken as such by eight individuals, and the consolidation of eight locations which have been taken up as eight separate claims.

It may seem unjust that the association claim of 160 acres requires but \$100 worth of work, while a consolidation of eight claims into one company requires \$800 worth of work, but such is the law. Work need not be done on each 20-acre tract of a location embracing 160 acres made by an association, for the appropriation of 160 acres by eight associated persons is accomplished by one location. An illustration of another phase of this portion of the mining law is found in the fact that a quartz claim 1500x600 feet requires \$100 worth of annual labor, but a fractional claim of much smaller dimensions requires as much labor as a full-sized claim. "The volume of work," says Lindley on Mines, "is not gauged by the size of the claim located. There is no sliding scale adjusting the matter according to area. In determining, therefore, the amount of annual work to be performed in connection with an aggregation of locations, each location is to be considered as a claim within the meaning of the law, regardless of the superficial area comprised in any one or more of them."

IN the case where A, a corporation, owning a group of claims upon which assessment work had been done up to Jan. 1, 1904, but no work or improvements made during 1904, the claims become subject to relocation Jan. 1, 1905. The fact that B was told he might relocate them gives B no legal rights in the premises, unless he was given written notice of abandonment by the company, the same being an official act of the board of directors, duly signed by them and the president. Without it B could not probably hold the property should the company seek later to dispossess him, as they might in the event of his making a strike. A held the claims by permission of the Government under the terms of the Federal mining statutes, which require A to comply with the requirements of the statutes or lose the claim by forfeiture. Having failed to comply with the statutes, A has no rights in the matter after Jan. 1, 1905, as the claims then reverted to the public domain on that date and were then subject to relocation by any other citizen. The only manner in which B could have secured any rights would have been under the original location, by beginning assessment work during December, 1904, and continuing the work until completed. C, in relocating the property, does so in accordance with the law, and unless B has the formal official notice from the company above referred to, C would be the only one having a legal right to the claims at this time. Had A been an individual, instead of a corporation, it would be somewhat different, and the intention of abandonment would be strengthened by the removal of surface improvements; but corporations are required to do all acts in a formal manner through its duly constituted officers. D, who relocated the claims Dec. 16, 1904, has no rights whatever, as he probably neither had the written consent of the company nor the right to appropriate the claims before Jan. 1, 1905.

THE fact that some portions of a vein are accompanied by a selvage or gouge, while other portions are "frozen" to the walls, is not always easy of understanding, though several explanations have been advanced to account for this phenomena in certain cases. The most reasonable theory, perhaps, is that the country rock adjoining veins is usually divided into large wedge-shaped blocks, and some of these blocks may be caused to move in one direction or another by the stresses which are constantly occurring within rock masses, while other blocks are not subjected to these movements to the same degree, or possibly not at all, and selvages, consequently, are not formed. Rocks are elastic, and admit of considerable bending without fracture if the pressure is exerted so slowly as to admit of a readjustment of the molecular structure of the rock. The movements of vein walls are various, for the striations found in one portion of the mine often do not agree in direction with those in another portion. A change of dip or strike in the vein would produce this condition in the event of movement in the walls occurring. In some places there are evidences of movements having occurred at different periods in different directions, which is also indicated by the striations on the walls crossing each other. Owing to these inequalities in the surface of the vein plane, one portion of the wall would be subjected to greater movement than other portions. Movements, which in one part of the vein results in selvage or gouge, may be dissipated by the fractures extending into the walls. In many instances the movements which have produced the selvages at the side of the vein have taken place since the formation of the vein, and the movement producing the selvage along one part of the vein has caused a fracture in the wall following some line of weakness, offering less resistance than the plane of the vein itself. In that portion of the vein beyond this branching off of the break the vein is found "frozen" to the walls. There are other conditions which might produce these results—mostly of a mechanical nature, and some, also, of a chemical nature. Some veins have two good walls with selvages or "let go" in one portion, a single clean wall in another, and no walls at all in a third. In some cases it is known that the portion of the vein having two walls is due to the prior existence of two parallel, or nearly parallel, fissures between which the mineralization took place. In the case of one wall, the mineralization occurred on one side of the fissure only, and in the case of "frozen" walls, the mineralization has occurred on both sides of the fissure and completely obliterated the fissure by replacement of the original material by quartz and other vein materials.

## The Mother Lode in Amador County, Cal.

Written for the MINING AND SCIENTIFIC PRESS.

The Mother Lode does not appear in its greatest width in Amador county, but its deepest and greatest mines are developed in that county, and the large and profitable production of the mines of that county on this mineral belt has made it a mining field of unusual interest to students of mining geology and mining methods, as well as to investors. There have been few disappointments in investments in mines of the Mother Lode in Amador, where the surface showing has justified the investment, and there have been some fortunate strikes in the way of unlooked for ore bodies discovered by systematic development. There is considerable difference in the character of the veins along the Lode in this county, but, on the whole, there is less variation in geological condition, possibly, than is found in some of the other counties through which the Lode passes.

In the southern portion of Amador, from the Mokelumne river northward to the vicinity of Jackson, the Lode appears as a series of approximately parallel veins and lenses or zones. Some of these are found wholly in the black clay slates (Mariposa beds), others in the amphibolite schists (altered greenstone tuffs), and a third class is found in part at contact of the black clay slates and the amphibolite schists. This section has been the scene of several large and unfortunate investments, but in view of the great success of some of the mines on the same Lode 2 or 3 miles farther northward it may be contended that some of these enterprises were justified by surface indications. Had they proven successful ventures, the managers would have won fame and fortune, but as some of them were not, the managers should not be held wholly responsible. There is a well-known adage that "good mines make good miners," and this will apply with force to some of the less fortunate miners of the southern end of Amador county.

In the southern limits of the town of Jackson is the Zeila mine, one of the most noted in the county. This mine has probably had the longest period of continued activity of any mine in Amador. It occurs almost wholly in the amphibolite schists, as a series of fahlbands, with numerous veins of gold-bearing quartz, between which the schist, more or less silicified, contains gold and auriferous pyrite. The Zeila apparently is isolated from the other mines of the belt, as nothing of value has as yet been developed either north or south of it in the immediate vicinity.

To the westward several hundred feet is a fissure in black slate, which is traceable in a generally northerly direction several thousand feet, but as this vein has not been followed continuously by mine workings, it is a question whether it is a single fissure or a series of fissures of uniform strike and similar characteristics. In Amador county, as elsewhere, miners are inclined to lay down arbitrary lines in indicating the course of an undeveloped vein, when, in fact, in a developed mine the vein is rarely perfectly straight for long distances, but swings from side to side in a more or less sinuous course, and its dip usually varies in like manner, changing from one angle to another. In view of these known facts it seems necessary to allow some latitude in assuming the strike of a vein which cannot be traced with absolute certainty on the surface. On this almost wholly undeveloped vein are found the Good Hope claim, in the southern part of the town of Jackson, and the Muldoon claim, about 4000 feet to the northward. Intermediate of these mines, there are several wells and prospect holes within the town of Jackson, all in a general line, which are probably on this same fissure, and all of them contain gold-bearing quartz of a character similar to that found in the great mines a little farther northward. The Argonaut and Kennedy mines are about a mile north of Jackson, on the foot wall vein of the Lode. This is one of the most interesting sections of the great Lode, because of the great extent and value of the mines developed on it at this place. The outcrop of the foot wall vein is found on the summit of the hill, near the Kennedy chlorination works, and is also exposed in a shaft sunk 60 feet through the andesitic cobbles and sand of an ancient river channel, back of the Argonaut hoist. Southward this ancient channel has been eroded, and the outcrop again appears on the surface, and may be traced almost without break to the Alma mine, on the hill west of Jackson. This outcrop occurs throughout the entire distance here mentioned, in the massive greenstone, which here along the surface is much decomposed. The vein itself varies in thickness from a few inches to over 12 feet, consisting of solid quartz, and the dip along the surface ranges from horizontal to about 35° to 40° to the eastward. In depth it becomes steeper and at about 800 feet is found to have an angle approximating 63°. At greater depth it becomes even steeper than this, but in still greater depth (2000 feet) shows a flattening tendency with a greatly increased size. The development of the Argonaut and Kennedy mines shows the outcrop vein to occur in the plane of a thrust fault, in which the hanging wall has been moved upward relatively

to the foot wall. In a raise in the Argonaut, a short distance south of the shaft, this is shown to be about 125 feet. It may be that there is also a longitudinal movement, though as to this the writer is unable to state. In the Kennedy mine, and also in the Argonaut, this foot wall vein has been worked more or less extensively from the surface downward, but no considerable body of pay ore has been found in this fissure along the surface outcrop, southward from the vicinity of the Argonaut shaft. A large amount of development was done on the Alma—shaft sinking, drifting and crosscutting to the extent of several thousand feet—but little ore of value was found. There still remain several hundred feet of this claim which have not as yet been proven.

The Argonaut-Kennedy fissure is often referred to as a contact vein. This is true in part only. The surface outcrop, as previously stated, is wholly in greenstone, which fact is prima facie evidence that it is not a contact. In depth the vein is found in part at contact of black slate and greenstone schist, and again wholly in the black slate, while in great depth there are large ore bodies in the amphibolite schist. In the deeper portions of these mines the vein assumes more the characteristics of a great zone of mineralization, in which are several veins or lenses, rather than the simple type of vein occurring in that portion nearer the surface. It is very probable that the Good Hope-Muldoon fissure forms a junction with the Argonaut-Kennedy vein at some place, but as far as known the point of union has not as yet been discovered. It may be farther south than the development has yet extended. It also seems probable in the present state of knowledge of this portion of the Lode that the former fissure will be found to be the principal ore carrier for some distance to the southward.

The Oneida mine adjoins the Kennedy on the northward, and as the workings practically have been connected there remains no doubt of the identity and continuity of this vein in these two properties. The topography of the ground in this part of the county has been largely determined by the course of the ancient river channels, the volcanic cap of which has to a great extent protected the softer slates and schists adjacent to the Lode from erosion. Were it not for this there is little doubt that the course of the Lode would be marked by a valley or cañon, as is the case in several sections northward where this protection has not been afforded. The vein continues with many of the characteristics common to the Kennedy, through the Oneida into the South Eureka, where the ground is much broken, there being several veins, with the usual characteristics—heavy black gouges, banded quartz and swelling ground—which are features of nearly all the important mines on the Mother Lode in Amador county.

Adjoining the South Eureka on the north is the Central Eureka. Here the vein has narrowed, so far as known, to a single great fissure, with an occasional branch into the hanging wall. This fissure in the vicinity of the shaft produced no ore of consequence until a depth of about 1000 feet from the surface had been reached. Below this level ore formed in a series of shoots, which growing longer and wider with depth eventually formed a large and valuable ore body. Near the north end of this property a rich shoot of ore was discovered and worked in early days. It was at that time known as the Summit mine. The mine is now developed to a depth of over 2000 feet. North of the Central Eureka are the Badger and Eureka claims, known as the Consolidated Amador. It is now more than thirty years since this property was in operation. Prior to that time it is credited with having produced over \$18,000,000. The workings are over 2100 feet deep and have been flooded for years. The writer has never had an opportunity to inspect the underground workings, but it is said by those who should know that this is a simple fissure occurring at contact of a greenstone hanging and a black slate foot wall. A peculiar feature of this mine, which may or may not have a bearing on the occurrence of the rich ore bodies, is in the fact that in this property the Mariposa slates have narrowed down to from 150 to 200 feet, while just north of the bonanza shoot the slate area suddenly widens to 1000 feet or more. In this connection it is of interest to note that at the Kennedy-Argonaut the slate strip is also comparatively narrow, and a similar condition is observable at the Keystone mine at Amador City. These may be merely incidental, but the geological fact is well established. At the Eureka mine little or no greenstone or amphibolite schist is found on the dumps, indicating that the workings were almost wholly, if not entirely, in the slate. In size the vein is described as varying from 3 or 4 feet to upwards of 100 feet in width. The ore was often phenomenally rich in gold, for so large a vein, producing much fine specimen rock. Early reports credit the mine with ore worth \$27 per ton which netted \$22. The vein, so far as known, continues northward into the Wolverine mine, which, however, has no record as a producer, though it is supposed that the vein in the Wolverine is identical with that found in the south end of the Wildman which adjoins it on the north, and that the continuity through the Wolverine is unbroken between the Wildman and the Eureka.

Many of those unfamiliar with the Mother Lode have formed the impression that the Lode is a single

great vein, occupying the plane of a contact fissure. How erroneous this idea is, is best known to the miners of the Lode. It is true that from the Central Eureka to the south end of the Wildman mine, a distance of about a mile, the vein apparently approaches this ideal, but to the northward and southward the Lode has many branches, and usually it consists of a number of veins having an approximate parallelism, the veins varying in character with the enclosing rock. In slaty rocks the vein generally has a banded or ribbon structure. In massive and schistose rock the vein is more or less massive, and on the contacts it is found banded adjacent the slate wall and more massive on the greenstone side.

In the Wildman mine a variety of veins occur. Here are found beautifully banded veins, solid massive veins, brecciated veins and granulated masses, the latter two classes indicating, together with the striations and grooves with polished surfaces, the intense pressure and movement to which these rocks have been subjected since the period of ore deposition.

(TO BE CONTINUED.)

## Rock Drilling.

Written for the MINING AND SCIENTIFIC PRESS by W. W. WORD.

A well written article appeared recently in these columns relative to power-made and sharpened rock drills. The deductions arrived at seemed clear and the points well taken, but much has been said on this subject by writers who see it from different points of view and each uses arguments which would seem to make his position impregnable.

The sizes and shapes of the bits for machine drills are as various and peculiar as the minds of men can devise. One of the new-fangled bits in use for a year or more at some of the copper mines in Michigan consists of the regulation cross bit forged so that a chisel part, about one-third the width of the drill, projects from  $\frac{1}{4}$  inch to 1 inch ahead of the cutting edges of the drill proper. This chisel part is forged in the center of the bit and parallel with two wings. The advantages claimed for it are that the chisel part, cutting ahead of the main part of the bit, prevents the bit from leading off or fitchering in seamy rock. Another peculiar bit which has many advantages claimed for it, and which is used to some extent in the Northern iron mines, is a single bit with two ribs or wings running along the sides and terminating about  $1\frac{1}{2}$  inch from the cutting edges. These wings or ribs do not carry cutting edges, but are intended to hold the drill in the center of the hole, and at the same time to give strength to the cutting part. It is said this drill will not rifle a hole or become fitchered. These kinds of drills are, however, expensive to make and resharpen unless a power drill sharpener is used, as the chisel part mentioned naturally wears faster than the rest of the bit. To renew this chisel part the wings have to be upset until sufficient stock projects ahead to form this important part, which operation is very expensive and laborious if undertaken by hand.

As to the gauges of drills, experience has shown that in hard rock the best results cannot always be obtained by having a uniform step or drop in the gauges; that is to say, the difference in sizes should be greater in the first three drills than in the last four or five, for the reason that the starters and first drills used have a greater area of rock to cut, and will consequently wear down more in a given depth than the smaller drills that follow. What this difference in sizes should be varies as to the character of rock to be drilled.

Opinions differ as to the size a drilled hole should be at the bottom, but usually a miner tries to get all the powder he can at the bottom of the hole; his object, ostensibly, is to break the rock to the depth he has drilled. There are few things that cause more annoyance and provoke more profanity with the miner than finding, after a round of holes have been fired, that a number of "stubs" or "butts" remain to be fired over again to square up the face of the drift or stope. In hard ground he usually lays it to pointing his holes too strong, which is sometimes the cause, but it would seem by a simple line of reasoning that if the full charge of powder could be placed at the bottom, where its force would be exerted from one place, instead of stringing it out from one-half to two-thirds the depth of the hole, better results would follow, as it is more likely the powder would break the rock to the bottom of the holes so that another full round could be put in without having to put in "pops" or shoot old "stubs" over again to square up the work.

If some genius would invent a practical drill or device that would chamber a hole, permitting the full charge of powder to be placed at the bottom, it is likely he would materially reduce the powder bills of mining companies and greatly enhance the miner's chances of a future in the bright hereafter.

## Magnetic Concentration in Australia.

Much interest is being manifested in the approaching system of concentrating the crude ores of Broken Hill Junction North under magnetic conditions. Experiments have already proved that, with lead at £12 per ton, silver at 2s 2d per ounce, and spelter at £20

per ton, the refractory sulphide ore characteristic of the mine can by magnetic separation be turned into a profitable commodity, and any advance in these metals will correspondingly increase these profits, or vice versa if there is a fall. Up to the present time on the Barrier attention has only been given to treating tailings and secondary products for market purposes by the magnetic, so that the concentration of

### Two Black Hills Mines.

Written for the MINING AND SCIENTIFIC PRESS.

Among the many successful mining enterprises in the Black Hills of South Dakota, the Wasp No. 2 has attracted attention. It was located more than ten years ago and is situated on Yellow creek, which

careful methods of mining and sensible arrangement of mill the costs were reduced to a figure where a good profit was possible from ore containing but \$4 to \$5 per ton. It is stated that at one period ore containing but \$1.60 per ton paid a small profit. One of the accompanying illustrations is that of the Wasp No. 2 mill, on Yellow creek. It is a dry-crushing mill, situated in a position where advantage may be taken of gravity in handling material. The ore is delivered to the leaching vats by belt conveyor running at a speed of 600 feet per minute, the time of filling being from two to two and one-half hours, and is found to be a less expensive way of filling than by cars running over the tanks, as was formerly the practice at this mill.

When the tanks are about half filled a strong solution (6 pounds KCy per ton) is turned on. Fifteen tons of this solution are run in and the charge allowed to stand three or four hours, occasionally longer, depending on the character of the ore. When the strong solution is started draining off, weak solution is run on to replace it, contact being continued an hour longer. Leaching then begins and the weak solution is continued to replace that running off until wash water is added. When the values in the solution are not greater than about 35 cents per ton the wash water is applied. Precipitation and cleanup are effected in the usual manner.

The ore bodies of the Wasp No. 2 and those of the immediate vicinity are all in the Cambrian, lying upon or in the quartzite. In the Wasp No. 2 is a large intrusion of porphyry, which is split into two branches going southward. There is a small displacement (8 to 20 feet) along these dikes, and the ore occurs in close proximity to the intrusion. Between the two branches of the dike was found an ore body 40 by 60 feet in superficial area, and 5 or 6 feet thick, which is said to have produced \$75,000. In this mine and several others near by was mined a quantity of wolframite (tungstate of iron and manganese) and a large amount of it was shipped to the smelter for the gold contained before the presence of the tungsten mineral was recognized. The ore is usually covered by a few feet of soft shale and soil, which is stripped off and the ore mined by open cut system. The drilling is done by means of a churn drill, the holes being 10 to 20 feet

deep, depending on the thickness of the ore body. These holes are "chambered"—that is, enlarged by shooting first several small charges of dynamite in the bottom of the hole, and later larger charges, and finally a heavy charge of black and nitro powder, which usually breaks a large amount of ground. One blast of this character is described as follows: The hole was drilled 19 feet deep and sprung with 5 sticks of dynamite. The second shot took 15 sticks, the third 75 sticks and the fourth 200 sticks (about two 50-pound boxes), the fifth 3 kegs of black powder, and the sixth with 3½ kegs of black powder. It was then thought the rock had been sufficiently shattered to blast. The hole was charged with 40 kegs of black powder and the blast fired, which, it is said, broke 3000 tons of ore, at a cost for labor and powder of \$550, or about 18 cents per ton of ore broken. The breaking of ore in this manner reduces mining expense to a low figure, and where conditions are such that the broken ore can be drawn off through a mill hole to a chute below the cost is still further reduced.

The Hidden Fortune Co., whose mill is also illustrated, owns a group of mines within ½ mile of the Homestake, and adjoining some of the mines of that property. In the early days these mines were opened in the Archaean schists, in which were found rich veins and zones of gold ore similar to those of the Homestake, but of comparatively small dimensions. In the Cheyenne mine, one of the group, rich specimen ore was found as early as 1878. The Bingham mine, another of the group, was sold for a large sum in the early days, but the property did not attract

marked attention until the discovery of very rich ore in the Cambrian on the Hidden Fortune by O. P. Grautz in 1899. The prospector was searching for wolframite, but found thousands of dollars in coarse gold.

A company was organized to operate the property and a mill built 3 miles below Deadwood and about 6 miles from the mine. For some reason the property has not been operated steadily, but it is now in the hands of new managers, and probably will be worked steadily. The ore from this property consists of two kinds, the free milling schistose ore of the Archaean and the quartzite ore from the Cambrian. Whether these two classes of ore can be suc-

Mill of the Wasp No. 2 Co., Near Kirk, South Dakota.

Hidden Fortune Mill, Near Deadwood, South Dakota.

raw ore by this method on the Junction North will prove a valuable object lesson. The crude sulphides in the mine as a whole are highly charged with rhodinite (manganese spar), and likewise with garnet sandstone, which makes them highly sensitive to electrical influences, and the metals become readily separated with high recoveries. The arrangements are complete, with the exception of the magnetic separators, eight in number, which are being constructed in South Australia. Experiments are being carried out at the Lithgow steel furnaces with silica sand recently discovered in the State, which, if successful, may obviate the necessity of importing silica.

joins the Whitewood creek near the town of Kirk. In its early history this mine produced more than \$500,000 from high-grade ore, which was shipped to the smelters. When the high-grade ore was exhausted the mine was closed down, for the low-grade ore would not pay the expense of mining, transportation and treatment. At that time the cyanide process had not yet been introduced in the Hills, but when this method of treating the oxidized ores of the Cambrian beds was worked out the Wasp No. 2 was one of the mines that was among the pioneers in introducing the cyanide process. The shipping ore had been rich, often exceeding \$100 per ton. The low-grade ore was worth but \$5 per ton, but by

cessfully treated by a single treatment is a question. At the Hidden Fortune mill both amalgamation and cyaniding are practiced. The capacity of the mill of sixty stamps is over 300 tons daily. The ore is crushed in the cyanide solution, in which respect it differs from other cyanide plants in the Hills.

### Gold Dredging in Oroville District, Cal.

Following is an abstract of the annual report of the Oroville Dredging & Exploration Co. of California for the year ending December 31, 1904, made by F. W. Bradley, president, to the stockholders of the company:

Our No. 1, or \$45,000 dredge, made the following record:

Cubic yards dredged.....	493,150
Gold yield per cubic yard.....	12.33 cents
Operating costs.....	5.62 "
Operating profit.....	6.70 cents or \$32,905.79
Improvement, taxes, insurance, legal and all other working expenses (except construction of No. 2 dredge).....	7,166.88
Surplus.....	\$25,738.91

Our No. 2 or \$75,000 dredge should be ready to begin work next month (January, 1905). Figuring on the data now available, the two dredges should make following average annual record:

	Cubic Yards Dredged.	Operating Cost Per Cubic Yard.	Probable Yield Per Cubic Yard.	Surplus.
Dredge No. 1 (first cost, \$45,000).....	530,000	5.30 cents.		
Dredge No. 2 (first cost, \$75,000).....	780,000	5.00 cents.		
Totals and averages 1,300,000.....		5.12 cents.		
Improvements, taxes and all other working expenses.....		0.88 cents.		
Total.....		6.00 cents.	9.5 cents.	3.5 cents.

Or a yearly surplus of \$45,500. Our prospect information indicates that after rejecting that portion of our land of doubtful value, the property should have a life of from thirteen to fourteen years at the above estimated rate of dredging.

C. H. Munro, superintendent, makes a detailed report of the company's operations, from which the following is taken:

**EXTRACTION.**—The prospect value of the area dredged, based on the average value of the holes in and near the dredged area, was 16.64 cents. The extraction table herewith attached, which is computed on these figures, makes the extraction 74% of the prospect value. The extraction amounted to 76.37% of the prospect value, based on the proportional or fractional areas as influenced by each prospect hole.

It would, therefore, be fair to call the extraction 75.18% of the prospect value, which is the average of the two methods of computation above referred to.

During the year just ended, Biggs No. 1 dredged 11.85 acres, handling 493,150 cubic yards, which yielded a gross bullion return of \$60,738.52, or an average yield of 12.32 cents per cubic yard, as compared with a gross bullion return of \$36,525.25, or an average yield of 8.45 cents per cubic yard for 1903.

**COSTS.**—The operating cost has been 5.62 cents per cubic yard, and the total cost, including all improvements, repairs, taxes, insurance, legal, office and other expenses (excepting Biggs No. 2 construction account), has amounted to 7.06 cents per cubic yard.

Comparing the capacity of the dredge and the cost of operation for 1904 with 1903, the capacity has increased from 39,551 cubic yards per month to 41,096 cubic yards per month, while the cost of operation has decreased from 6.48 cents per cubic yard to 5.62 cents per cubic yard, and the total expense from 7.71 cents to 7.06 cents per cubic yard.

The bullion yield has increased from 8.45 cents per cubic yard to 12.32 cents per cubic yard.

**REPAIRS.**—Aside from the ordinary repairs on the dredge, a new revolving screen was installed at a cost of \$1600, and the 1 H. P. motor used for priming the water pumps and cleaning up was replaced by a 3 H. P. motor at a cost of \$127.55.

**FUME REPAIRS.**—During the floods last February 500 feet of the flume and trestle were washed away. The rebuilding of the flume and trestle and repairs at the pump station cost \$357.40.

**IMPROVEMENTS.**—The blacksmith shop equipment has been enlarged at a cost of \$547.45 by installing a 5 H. P. motor, with transformer, a forge, blower, emery wheels, grindstone and small drill press.

**BIGGS NO. 2 CONSTRUCTION.**—The hull of Biggs No. 2 is completed and the dredge was floated the first of the year. The contractors are now installing the machinery and the dredge will probably be ready for operation about the middle of February, 1905.

BULLION TABLE.

### Recovery of Tin From Scrap.

The treatment of new tin scrap, known as "detinning," has become of considerable importance in the United States, says the Journal of the Franklin Institute, and at least ten companies were actively engaged in this special branch of the industry during the year 1903. The average yield from tin scrap is approximately 2% of metallic tin. In addition, a

large number of small concerns in the principal cities recover the tin from old tin cans and similar material by a smelting treatment in a furnace, the tin being obtained in the form of solder, which is either used as a basis for making new solder or is treated chemically to yield metallic tin or tin salts. The residue of scrap iron is generally utilized in the manufacture of sash weights and other casting of inferior quality of iron.

### Ore Washing in Cripple Creek, Colo.\*

[FROM A STAFF CORRESPONDENT.]

The ore bodies of Cripple Creek district, Colorado, are peculiar in that, generally speaking, a large amount of sorting is necessary after breaking the ore down in the stopes. In some of the mines the ore is roughly hand-sorted under ground, in others all the rock broken in the stopes goes to the surface where the sorting is done by various methods, partly by hand and partly by mechanical means. The values are usually associated with soft material, while the hard rock of the vein or zone of mineralization is almost destitute of value. This condition renders the cost per ton of mining unusually expensive. Little ore is hoisted to the surface in Cripple Creek under \$3 per ton, and most of it costs from \$10 to \$15 by the time it is ready for the mill or smelter, owing to the large amount of waste eliminated from the tonnage broken. The conditions obtaining here have resulted in the introduction of various devices for cleaning of the ore and the separation of the rich fines from the coarse waste.

It is a common practice among several of the mines in the Cripple Creek district to wash the ore before sorting. As a rule the deeper mines are wet, and in blasting much of the ore is broken into fine particles, which adheres to the rock. When it becomes dry and in handling the ore in this dry condition the fine particles of ore, which contain good values, are practically lost. Several styles of washers are in use. A number of the mines are operating the Crane washer, while some have installed washers of their own design, and others do not wash the ore, but sort it when dry, or as it comes from the mine. All the mines that have adopted some sort of washer are well satisfied of the necessity of this process and with the results obtained, and in several instances are increasing the capacity of the washer and improving on the methods now in use.

At the Portland mine the ore and waste rock are first run over sorting tables, and the ore is separated from the waste by men stationed at the tables. The waste passes through a chute into hoppers. The bottoms of these hoppers are lined with grizzly bars or perforated sheets of metal, and as the rock passes into these hoppers it is separated into thin layers. Above the rock is a coil of perforated pipes, from which a large number of jets of water fall onto the rock. The fine dirt passes down through the perforated plates or grizzlies into tanks and settles, and the water is again used for washing. The waste rock too large to go through the grizzlies or perforated plates is passed along by a rubber conveyor belt where men are watching for any ore that may have escaped the sorters.

The ore from the C. K. & N. mine is first run over a grizzly and screen underneath and the fines taken out, and the coarse rock sorted by hand without washing. The screenings are shipped without sorting.

The Old Gold Co. hoists its ore to the surface in buckets and dumps into cars and then trams to the ore house, where the ore is run over ¼-inch mesh screens. The screenings fall into a bin and are ready for shipment. The coarse stuff goes to another bin and from that is cobbled and hand picked, the waste being sent to the dump, the shipping ore going to the bin below. The bottom of the picking table is composed of a sheet iron plate with ½-inch round holes. Above the table is a pipe line, which carries the wash water along the picking table. At intervals there is a rubber hose attached to the pipe and as water is

\* See illustrations on front page.

desired it is turned on by the man in charge. All fine dirt adhering to the rock is washed through the bottom of the table into a tank below. This material is dried and shipped with the screenings.

The ore is taken from the bins at the Lonaconing through a chute, where there is a spray of water continually going over the ore. In the bottom of the chute is a 2-inch screen to permit of the fine dirt passing through to the tank below. The water passes through three tanks and after it becomes thick with slimes it is pumped up into the fourth tank and allowed to settle for four or five days, when it is pumped into the storage tank and used over again. In this plant there are four tables used for sorting. This washer is capable of handling 100 tons per day. The water is kept warm by live steam from the boiler.

As the ore is hoisted to the surface at the Elkton mine it is trammed to the ore house and dumped over a grizzly. Under this grizzly is a wire screen with 1-inch mesh. These screenings drop into a bin below and are taken from there to the loading bin. They do not pass through the washer. The coarse material passes to a large bin and from there it is drawn off through a chute, where it is washed by a spray of water as it falls onto a sorting table or shaking feed about 8 feet long. At this point several men are engaged in sorting the waste from the ore. The waste is thrown into cars and trammed to the outside of the building, and from there is taken up a 15° incline by a small friction clutch hoist to the dump. The ore as it leaves the sorters is delivered to a Blake crusher, where it is crushed and passes to an elevator and lifted 31 feet. This product is then discharged into a circular, perforated, revolving screen. This is the Crane washer. This revolving screen is 40 inches in diameter by 12 feet long. Where the ore is received into the screen the perforations are 1/2 inch; in the center of the screen they are 1 1/2 inch and at the discharge end 1 1/2 inch. The screen drum is carried on rollers and makes about eight to twelve revolutions per minute. The fine ore is screened out, dropping automatically into the bin underneath. The coarse ore is delivered into the second drum for washing. The second drum contains a steel spiral screw on the inside. This screw revolves at the rate of speed corresponding to the screen drum, and rests in a tank, so that about one third of it is submerged in order to wash the fine dust from the coarse rock, the water carried up by the screw being drained back into the tank by the rows of 3/4-inch holes near the delivery end. The drums are driven by a sprocket chain. The tank underneath the drum serves to hold the washing water and collect the slimes. A manhole at the bottom of the tank permits the removal of the slimes as often as necessary. The slimes when drawn off from the tank are placed in another tank or vat, where they are dried and then sacked for shipping. The ore passes from the washer onto a picking belt, which is run on an incline of several degrees in order to give space below for the ore to be thrown into bins instead of into cars. At each side of this belt there are several men sorting the ore from the waste. The waste is still retained by the conveying belt and discharged into a hopper, where it is drawn off into cars and trammed to the dump. The management is convinced that the belt should be arranged so as to deliver the ore and allow the waste to be picked out, as there is very little waste remaining on the belt after washing and picking below. The ore which has been thrown into the bins below is drawn off onto a conveying belt and run through a large crusher and crushed to about 1 inch. After passing through the crusher it is elevated 60 feet to the top of the building, where automatic samplers are used for sampling the product. The ore that is not taken out by the sampler is then passed down through a chute to the loading bins. This company operates its own sampler in connection with the washer and is able to tell within a few dollars how much they have made or lost the day previous. The screenings which do not pass through the washer are sampled the same as the ore. The screenings are not put through the crusher, but are carried by an elevator to the sampling room at the top of the building.

The Vindicator ore is sorted dry and the waste washed. The waste runs over a grizzly and perforated plate, then over a screen where there is a heavy spray of water, then onto a belt, where it is taken to another building and again washed and sorted by hand. This belt is 202 feet in length. The waste goes to a bin below, where it is loaded into railroad cars and hauled away. The Vindicator Co. is cramped for ground. The slimes from the waste are caught in settling tanks underneath the grizzly and perforated plates and allowed to settle and dry.

The El Paso mine brings all the ore and waste to the surface as it is broken in the mine. The ore is hoisted in cars holding 22 1/2 cubic feet of broken ore. The gallows frame is 84 feet in height, and from the collar of the shaft to where the ore is taken from the cage is 52 feet. The trammers take these loaded cars to the ore house where it is first run over a grizzly. Underneath this grizzly is a screen having 1/2 inch openings through which the finer material passes into a separate bin. The screenings are sampled, and if found to contain values enough to pay to ship are taken to the shipping bin, otherwise they go to

the dump. The screenings are not washed, but are shipped dry. The coarse rock, which has failed to pass through the screen underneath the grizzly, is drawn from the bin through a chute over a perforated metal sheet. These sheets are under all of the ore bins and are a part of the washer. The openings in the steel plates are 1/2 inch. Across this chute, and above the ore, is a horizontal pipe containing water under thirty-five pounds pressure. As the ore comes down the incline the spray of water is turned on and the dust and fines are washed off into tanks below where it is allowed to settle; the water after being settled is pumped back into the storage tank and used over again. At the lower end of the incline chute is a bench or sorting table, the top of which is made of sheet steel. On each side of this table is a man sorting the waste from the ore. If there is more waste than ore then the ore is picked out and the waste thrown into cars and trammed to the dump. If more ore than waste the ore is sorted out. In any case the ore is trammed to the shipping bin and the waste to the dump. This company does not have any picking or conveying belts. Everything is sorted on tables and trammed out in cars. Should the sorters find a large piece of ore containing ore and waste it is thrown on to the cobbing table where it is broken up and sorted. The water used in spraying the ore is warmed, during cold weather, by the exhaust steam from the hoisting engine. The water which is used in spraying and which passes through the steel plate to the tanks below is settled in three different tanks, the first one being a long tank where about nine-tenths of the washings are caught. It is then drawn into another tank and partially settled and from there to a third tank. The fines and slimes are thoroughly dried by steam. About four tons of slimes are caught through the washer each day, and about seventy tons of sorted ore are handled. The tailings will average very near to what the shipping ore runs. They have ten sorting tables and are increasing the capacity by five more.

One of the engravings herewith illustrates the Crane washer on the Abe Lincoln mine in Poverty gulch. The method of handling the ore at this property is practically the same as at the Elkton, with the exception of the sampling of the ore. There is also illustrated the picking belt and discharge end of the washer on the Last Dollar mine. These all handle the ore in about the same manner with the exception of a very few slight details.

## THE PROSPECTOR.

The rocks from Forbestown, Cal., are determined as follows: No. 1. Grano-diorite of normal type in which are seen quartz, feldspar—both orthoclase and plagioclase, black mica and dark green hornblende. The rock is very little altered. It may be the country rock for many veins, and should not be looked upon as unfavorable for mineral veins, for some of the best mines in the United States are found in rock of this description. No. 2 is also a granitic rock, apparently from the description and from its appearance a dike rock. It is essentially granulate. No. 3 is quartz with a little iron sulphide, and a bluish mineral in a thin film, which may be either molybdenite or graphite, probably the former; the quantity is too small to determine. This rock looks like a gold-bearing ore, and should be carefully tested, both by panning and by assay.

The rock specimen from Elmore county, Idaho, is a granitic dike rock, in which nothing remains in normal condition except the quartz, the feldspar (orthoclase) having been altered to halloysite, or a mineral closely resembling it. A small amount of white secondary mica is also present, either a remnant of the original muscovite, or a secondary mica derived from the alteration of the feldspar. This is a phase of the alteration of granitic rocks, particularly when occurring as intrusive masses, which is not uncommon. Although the rock does not show distinct schistose structure, it has been subjected to severe interior strains due to great compression and more or less movement. This is evidenced by the striations which may be seen on the softer portions of the rock and also in part by its complete alteration. Feldspar does not always alter into kaolin, but into various other substances as well, as in the present case.

The three samples from Placerville, Cal., are: No. 1. (black rock) bornstone, a variety of flint largely silica; No. 2 (gray) and No. 3 (gray) are similar—fine granular flint. All of these rocks are probably of concretionary origin, and may have been formed in limestone. Many such rocks are found in the ancient river gravels in the vicinity of Placerville, Cal.

The dark brown rock from Phoenix, Ariz., marked W. E. T., is apparently a much altered rhyolite in which what was probably either augite or hornblende has been altered to serpentine. There is also a development of calcite, due to alteration. There are numerous amygdulæ present, indicating that the rock was originally vesicular.

## Accidents in Mines.

TO THE EDITOR:—The remarks contained in the issue of the MINING AND SCIENTIFIC PRESS of Feb. 14, referring to the bill recently introduced in the State Senate of Illinois, providing that operators of mines shall provide men whose duty it shall be to load and blast holes, are of considerable interest and importance. Should this bill become a law, it will no doubt be welcomed by both mine owner and miner.

The necessity of adopting such measures in metal mining—not alone referring to the use of explosives, but covering all branches of mining work—is impressively emphasized by perusal of the statistical references to accidents sustained, over any period, in the coal mining industry:

The writer is not aware that any such complete records are kept in this country with reference to accidents in metal mining, and although the conditions of operation in coal mining, as well as, possibly, the standard of unskilled labor, would not admit of applying these figures to metal mining, they carry a good deal of significance and certainly reflect the importance of providing equally stringent laws in order that the casualties in an industry of as much importance as metal mining may be lessened.

The careless or ignorant use of explosives is but one of the dangers accompanying the work of mining as usually carried out in this country. The writer only recently called attention to the indifferent use of mine signals, while it is apparent to any engineer that a periodic examination of underground methods, including timbering, ventilation, lighting, condition and number of outlets, water or gaseous accumulations, etc., as well as bauling apparatus and boilers, would greatly decrease the number of accidents.

From an economical point of view, it appears doubtful if it is always advantageous to employ special men to load and blast all holes in underground work, as it does not seem likely that such a man, even though he possessed a good general knowledge of the mine, would be able to blast to the best advantage—that is to say, in the order of blasts and the quantity of powder used—unless, of course, he personally directed the work of drilling.

One method of lessening the accidents due to the careless and ignorant use of explosives is in the issue of "blasting certificates" to all miners who, after examination, have shown that they have a good general knowledge of the use and dangers of powder. In cases where accidents occur, and carelessness is shown, this certificate is cancelled.

One would think that a man who had spent say ten years at mining would be quite competent to undertake blasting operations without peril to himself, or others who might be within the danger zone, but experience in the examination of men in countries where blasting certificates are required show that a great many men who apply for work as miners have little or no knowledge of the use of powder, and are often ignorant of many other important considerations.

According to the report of the Bureau of Mines of Pennsylvania on the anthracite coal mines, the total number of deaths and injuries inflicted upon persons employed in and about the mines, with the average per 1000 employees, for 1903 was as follows:

	DEATHS.		INJURIES.		TOTAL.	
	Num.	Per 1,000.	Num.	Per 1,000.	Num.	Per 1,000.
Inside the mines.....	426	4.17	1,127	11.04	1,553	15.21
Outside and on surface. 92	1.85		198	3.98	290	5.83
Totals .....	518	3.41	1,325	8.73	1,843	12.14

An analysis of the accidents above recorded shows the following distribution, underground and on the surface:

	Fatal.		Non-fatal.		Total.
	Fatal.	Non-fatal.	Fatal.	Non-fatal.	
Inside the Mines.....	426	368	181	207	578
Falls of coal, slate, etc.....	210	70	249	319	
Mine cars.....	70	70	249	319	
Explosions of gas, etc.....	26	181	181	207	
Explosions of powder, etc.....	17	55	72	150	
Premature blasts.....	38	112	13	44	
Falling into shafts, etc.....	31	13	2	23	
Crushed at batteries.....	2	2	1	7	
Kicked by mules.....	6	17	6	17	
Suffocation by gas, etc.....	6	1	2	4	
Miscellaneous.....	22	129	22	151	
Totals .....	426	1,127	181	1,553	
Outside of Mines.....	92	60	25	59	105
Cars.....	39	34	4	5	
Machinery.....	25	34	4	5	
Suffocation in chutes, etc.....	4	2	2	4	
Boiler explosions.....	2	2	2	4	
Miscellaneous.....	22	96	22	118	
Totals .....	92	198	25	290	
Grand totals.....	518	1,325	206	1,843	

The percentage of the more important causes of accident to the totals were as follows:

	Fatal.		Non-fatal.		Total.
	Fatal.	Non-fatal.	Fatal.	Non-fatal.	
Inside of Mines.....	426	368	181	207	578
Falls of roof, etc.....	49.3	33.7	22.1	20.3	
Mine cars.....	16.4	16.1	13.3	13.3	
Gas explosions.....	6.1	12.9	14.2	14.2	
Premature blasts.....	12.9	13.8	15.0	15.0	
Other causes.....	15.3	14.3	15.0	15.0	
Outside of Mines.....	42.9	33.3	27.2	20.3	36.1
Cars.....	27.2	17.2	49.5	43.6	
Machinery.....	30.4	17.2	49.5	43.6	
Other causes.....	30.4	17.2	49.5	43.6	

The distribution of the employees is, as the report

points out, of more than ordinary importance. The number and classification is as follows:

Position.	Number.	Per Cent.
Mine foremen.....	360	0.4
Assistant foremen.....	276	0.3
Fire bosses and assistants.....	841	0.8
Miners.....	36,823	36.1
Miners' laborers.....	27,533	27.0
Drivers and runners.....	11,251	11.0
Door boys and helpers.....	3,087	3.0
Pump men.....	850	0.9
Company men.....	9,050	8.8
All others.....	11,824	11.7
Total.....	102,055	

These figures show that 67.2% of the labor was employed underground.

James F. Roderick, chief of the Mining Bureau, comments on the figures as follows: "The occupations of the 426 persons killed inside were as follows: Miners and miners' laborers, 312, or 73.24%; drivers or door boys, 58, or 13.61%; all other occupations, 56, or 13.15%."

Of the 102,055 employees underground, 64,356, or about 63%, were miners or miners' laborers, among which class over 73% of the fatal accidents occurred. For every 1000 miners employed 5.49 lost their lives, and for every 1000 miners' laborers employed 4 lost their lives.

These figures indicate clearly that the occupations of the miner and his helper is of an extra hazardous nature.

Of the 1553 accidents underground during 1903, 222, or 14.2%, were due to explosions of powder or dynamite, or premature blasts.

According to F. L. Hoffman, during the year 1903 there were 551,874 men employed and 1760 deaths in American coal mines, which amounted to a rate of 3.19 per 1000 employed. From 1894 to 1903 there were 4,439,732 men employed and 13,048 deaths, or a rate per 1000 of 2.94.

An international table prepared by Mr. Hoffman for the five years, 1898-1902, is very interesting. Including fifteen countries, there were employed 10,473,967 men. The total number of killed were 19,151, or a rate of 1.83 per 1000 employed.

Continuing his remarks, he says: "Assuming that the average annual rate of 1.83 per 1000 holds good for the remainder of the world (estimating the approximate number of persons employed in coal mining to be 2,500,000), we have it that, on the average, about 5000 persons annually are killed in the world's coal production." If we go further and apply the figure 14.2% as being the proportion of injuries due to the use of powder or other explosives, the annual casualties are shown to be no less than 710 persons.

If this be so of an industry which is under Government supervision and recognized organization, what would be the sacrifice rate per 1000 employed in metal mining?

Under proper supervision the dangers attached to mining should be largely theoretical and the work as free from hazard as many of our other industries.

Experience shows that, if left to the companies, reforms are limited by the sentiment of the individual manager, and often, in his desire to economize, not only are incompetent men employed on responsible work, but repairs to plant are delayed, which are a constant danger to the employees.

To the company or corporation, mining under limited Government supervision should be welcomed.

To the State it is a duty, and would exhibit a desire, that the industry should at least reach the same standard as that established in other countries.

To the miner, such qualifications as are exacted in countries where mining regulations are prescribed, are a certain guarantee of equality of knowledge.

The industry in California has surely reached a stage which warrants the adoption of regulations and the creation of power to enforce them.

F. C. ROBERTS.

Berkeley, Cal., Feb. 14.

The subject of the above communication is one of interest to every miner, and all will agree that it is desirable that the risk to which the miner is exposed should be reduced to a minimum, and in American metal mining districts most of the safeguards found about mines under Government inspection are afforded the miner. The high death rate and large number of non-fatal accidents, shown by the reports above referred to, were the result of the operation of coal mines. In metal mines the accidents do not generally reach so high a percentage, and are usually of a somewhat different character from those occurring in coal mines. The reports of those States having mine inspectors show a death rate considerably below that above quoted, and records kept in those States having no inspector do not show a higher rate. The State Inspector of Idaho, in a report just issued, gives a death rate of 1.3 for each 1000 men employed in that State. That in Colorado is somewhat higher. California has no inspector, but it is known that the death rate is low and the greater number of accidents of a character which no inspection nor Government supervision would have prevented. These are mostly due to premature blasts or drilling

into "cut-off" holes in shaft work. A bill has been introduced the present session in the State Legislature of California which provides for one inspector and an assistant whose duty it shall be to examine every operating mine in the State, inspect boilers hoists, cables, mine methods and a score of other more or less necessary things. It requires that the inspector be a mining, mechanical and civil engineer of not less than fifteen years experience in active mining. The salary is \$3000 per annum. A man competent to properly fulfill the requirements of the bill is worth five times the salary provided for in active mining work. If the bill were to become a law the mine inspector could not meet the demands of his office for the reason that it would be impossible for him to properly cover the ground. Legislation prescribing the methods of operating mines is always well intended, but it very often is impractical and falls short of supplying the relief sought. The miners themselves possess the remedy and they usually demand that the mine be operated in a safe manner. It is rarely, indeed, that accidents in mines are anticipated. Men are usually injured in some unexpected manner. A few days ago several men were killed by the falling of a cage at Butte, Montana, when an 8-inch flat steel rope broke which a few minutes previous had hoisted several tons of ore and cars. No mine inspector, had he been present, would have had the slightest suspicion of danger under the circumstances. It is useless to post a notice at the collar of the shaft, or at the station below, cautioning men not to walk into the shaft. Yet this is what they sometimes do. Most of the accidents in mines are the result of the carelessness of the miners themselves, as they will admit, and legislation against this kind of danger is useless.

### The Center Star Mine, Rossland, B. C.\*

Written by L. H. COLE.

The Center Star mine at Rossland, B. C., is located on the slopes of Red mountain northwest of the city. It is bounded on the west by the Le Roi, on the northwest by the War Eagle and Iron Mask, northeast by the Idaho and southeast by the Nickel Plate.

It is 1500 feet long by 600 feet wide, and was located in 1890.

The ore of this mine consists of iron and copper sulphides (pyrrhotite, chalcopyrite and pyrite, accompanied by arseno-pyrite). The principal value is in gold, which is chiefly in the chalcopyrite, but the copper makes an important addition, and there is always a small amount of silver present.

The veins vary in width from a few inches to 40 or 50 feet, and the pay shoots in some cases extend from wall to wall, while in others only parts of the veins are enriched. Sometimes the walls are very indistinct and the values run into the country and gradually decrease without any sharp line of division between ore and country.

The mine consists of several veins, either extensions from bordering claims or veins starting in the claim itself. The main Center Star vein, however, and the one in which most of the work is done, is the large shear zone fissure consisting of parallel platings of the rock produced by shearing under high compression. This vein runs along the southern slope of Red mountain and appears in the Le Roi mine; it has a dip varying from 60° to 70° and a strike that is approximately N. 68 E. It varies greatly in width and is cut by a large number of dykes and faults.

The Center Star and War Eagle mines are under the same management, and the offices are placed so as to be convenient to both.

The collar of the main shaft is located 500 feet from the west end line and 225 feet from the north side line of the claim. Over this shaft is erected the shaft house. The hoisting engines are on the hanging wall side, while the back part of the shaft is occupied by the ore bins.

Adjoining the shaft house and connected with it by two tram-car tracks is a 40x70 foot mill for framing of mine timbers, having the latest appliances for framing square sets and shaft timbers by power. This timber framing machinery was built by the Denver Engineering Works. A 48-inch swinging crosscut and rip saw complete the equipment, which give ample facilities for supplying the mine with framed timbers in the least time.

The War Eagle and Center Star hoists and Center Star compressor are all supplied with steam from the Center Star boilerhouse, which contains four horizontal tubular boilers (5x15 feet) of 100 H. P. each, carrying a steam pressure of 100 pounds, and three (88-inch by 16-feet) Scotch marine high pressure boilers carrying a steam pressure of 130 pounds and

having a capacity of 175 H. P. each. The fuel used is Crow's Nest Pass coal.

**PROSPECTING.**—Prospecting and development were started in the usual manner on the Center Star claim. The veins were exposed by surface stripping in several places and prospecting shafts were sunk on the veins. Two tunnels were run in on the ore, and from these tunnels prospecting proceeded by means of crosscuts, drifts, winzes and raises; when it was considered that the mine was sufficiently proven the main shaft was sunk. Work on this shaft proceeded at three different points simultaneously, viz.: sinking from the surface, raising from the second level, and sinking from the second level; the mine is now worked entirely through this shaft. The collar of the shaft is 3688 feet above sea level. The shaft has a dip of 70°. There are three compartments, two of which are used for skips, while the third is used for a man-way and for the ventilation and compressed air pipes. Each compartment is 5 feet square, inside measurement. From this shaft eight levels are worked, varying from 125 feet to 175 feet apart on the slope.

At each level a large station is cut out and the ore loaded into the skips from large pockets under the level. From the station crosscuts and drifts have been run in different directions to locate and work the ore bodies.

**DRIFTING.**—Where possible, the drifts are driven along the foot wall, where, as the rock is extremely hard, no timbering is required.

The average advance per round of holes is 4.5 feet, working one machine two shifts per day. The total

Method of Placing Holes in Blasting at Center Star Mine.

advance for a month varies from 70 feet to 100 feet; the grade of the drift is  $\frac{1}{4}$  of 1%. Drifting is always kept well in advance of ore extraction.

The raises are put in at irregular distances along the drifts, and are usually of two compartments, one a man-way and the other an ore chute.

**DIAMOND DRILL WORK.**—Two sizes of drills are used, one of 1½-inch core diameter, and the other with 1¼-inch core diameter. The machines are seldom used for boring over 300 feet.

In starting the drill, especially for those drifts in which tramming is carried on, a short crosscut is first blasted out to give room for operating the machine without interfering with other work. The rods are square threaded and are in 5 feet lengths; they are pulled in 5 feet to 10 feet lengths, according to the space available behind the drill. The average length of the core pieces saved is from 5 inches to 8 inches, but often the length of the core barrel is kept intact.

The drill engines are screw fed, and fitted for 300, 700 and 1000 revolutions per inch of advance. Their ordinary speed is 300 revolutions per minute with a maximum of 1500 revolutions per minute. The water is pumped through the drill rods by a small independent force pump run by compressed air. In an eight-hour shift, the progress made is about 10 feet.

Since the rock in which the drilling is carried on is very hard, the bits require to be reset frequently, drilling about 12 feet before resetting is necessary.

If the drill hole is not deep, the rods are pulled by hand, but if 200 feet, or so, the work is too severe, and a drum is then used on which is coiled the wire rope.

The core, after it has been examined and sampled,

\*Abstract Trans. Canadian Soc. Civil Engrs.

is placed in trays and put on shelves in the core house for future reference.

**NARROW STOPE.**—A large part of the workings consist of narrow stopes less than 15 feet wide. Having carried up the raise a sufficient height, stoping begins at the lowest limits of the pay ore and the stope is driven to the boundary of the pay shoot. Round stulls are used and a close floor of lagging is spiked on the stulls; stoping above the floor then commences.

The broken ore is kept close up to the face so as to have a good footing for the machine men.

When the pay ore begins just above the drift, a raise is not kept in advance of the stoping, since the whole back is worked as a stope. In this case, there is a permanent tight floor left above the drift.

**WIDE STOPE.**—For stopes of a width greater than 15 feet square sets take the place of stulls. The length and breadth of the ore body is first determined and sill floor laid down. Breaking down the ore from the back is then started. Enough space is always excavated above the last floor to leave room for drilling the back. For a change of width in the ore body, the stope is extended by attacking the hanging or foot wall, or by leaving out as many sets as is necessary, according as the vein widens or narrows.

(TO BE CONTINUED.)

### Map of Lake City, Colo., Quadrangle.

The range of altitude in the Lake City, Colo., quadrangle amounts to over 6300 feet, extending from an elevation of about 8000 feet above sea level on the Gunnison river, in the northeastern portion of the quadrangle, to the summit of Uncompahgre Peak, the loftiest point in southwestern Colorado, a massive mountain that rises to a height of 14,306 feet.

A portion of this quadrangle is embraced in the San Juan mineral district, and most of the mines in this quadrangle are along or near Henson creek. Much gold and silver has already been taken from this area, and it is believed that there will now be renewed activity in this district.

Lake City, the principal town in the area, is in the southeast corner of the quadrangle, at the junction of Henson creek with the Lake Fork of Gunnison river. It is the terminus of a branch of the Denver & Rio Grande narrow gauge railroad. Well built wagon roads lead from it to the neighboring mining camps.

Along the valley north of Lake City are various ranches on which crops of hay and vegetables are raised with the help of irrigation.

The horizontal control for this map was furnished in part by the transcontinental triangulation of the United States Coast and Geodetic Survey, from which extensions were made to secure the necessary positions by J. F. McBeth of the United States Geological Survey, who also did the topographic work. The map may be obtained for 5 cents on application to the Director of the United States Geological Survey, Washington, D. C.

### The Sturtevant Sampling Outfit.

The two machines described herewith are the latest addition to the line of Sturtevant machinery. The laboratory fine crusher is built on the same lines as the large crushers of this type and has special adaptability to cleaning. The machine is built in two sizes, with jaw openings 2x4 inches and 2x6 inches. The one illustrated is the 2x6-inch size, which weighs about 600 pounds, has a capacity of from 250 to 600 pounds per hour, crushing to sand size without screens. The front head and stationary jaw may be easily removed when both crushing surfaces are exposed for cleaning after each sample. The jaws and shields are of manganese steel, the toggles of bronze, working in tool steel seats. It is built for fine work and designed to crush hard ore to  $\frac{1}{4}$  inch and finer without clogging. The 2x4 crusher may be run by hand or power if desired.

The special sample grinder is designed to take the product from these crushers, or reduce hard or soft ore crushed to  $\frac{1}{4}$  inch and finer to 200 mesh, without screens, and it is adjustable for coarser work by turning the hand wheel. From a view of these devices it would seem as if the bucking board would soon be a thing of the past, except for very small lots of ore. This sample grinder is conveniently accessi-

ble, its grinding discs swinging open like a door, for cleaning or replacing the discs or plates.

Full particulars may be obtained by addressing the Sturtevant Mill Co., Boston, Mass.

### Gold Mining in Rhodesia.

NUMBER III.

Written for the MINING AND SCIENTIFIC PRESS by F. C. ROBERTS.

A comprehensive idea of the capital required in the full equipment of a mine upon a 20-stamp basis may be gathered from the following figures, which pertain to a plant recently completed by the writer:

#### TOTAL COST OF ERECTING A 20-STAMP MILL AND NECESSARY EQUIPMENT.

	Total Cost.....	Cost per Stamp.	Percentage of Total Cost.....
20-stamp mill (1300 lbs.) with timbers, shafting, pulleys, etc.....	\$ 48,951 38	\$ 2,447 58	23.9
Two crushers, each having a capacity of 10 tons per hour.....	3,407 70	170 38	1.6
H. P. half of horizontal tandem, compound, Corliss engine.....	8,850 61	442 53	1.3
Two mill boilers, 75 H. P. (type, multi-tubular).....	12,853 91	642 69	6.2
Economizer.....	834 74	41 73	.5
Totals.....	\$ 74,898 34	\$ 3,744 91	
<b>SHAFT PLANT.</b>			
Head gear (pitch pine), height 40 ft., capacity in bins 80 tons.....	\$ 8,163 31	\$ 408 15	3.9
Holting engine 40 H. P., geared.....	4,212 19	210 60	1.9
Boiler 50 H. P. (multitubular type).....	6,079 04	303 95	2.0
Economizer.....	368 60	18 47	.16
<b>ELECTRIC PLANT.</b>			
60 K.W. generator, 20 H. P. motor, 10 H. P. motor, auxiliary engine, wiring, lights, poles, etc.....	14,375 79	718 29	6.9
<b>PUMPING STATION.</b>			
3-throw horizontal pump, capacity 12,000 English gallons per hour.....	1,912 76	95 63	.93
<b>WORKSHOPS.</b>			
Lathe, screwing machine, saw bench, threading machine, meal mill.....	5,036 82	251 84	2.4
Assay plant.....	1,971 52	98 57	.98
Water Service: Pipe line, steam piping, etc., including 3100 ft. 6-in. pipe.....	9,068 39	453 41	4.4
Retorts, etc.....	592 72	29 63	.3
Caleining furnace.....	700 51	35 02	.3
<b>CYANIDE PLANT.</b>			
Double treatment, capacity 2800 tons per month.....	38,740 88	1,937 04	18.9
Buildings, quarters, etc.....	38,319 81	1,915 99	17.8
Totals.....	\$204,370 65	\$10,218 50	

In order to show the comparative cost of plant in New York and F. O. R. Bulawayo, the figures referring to the cost of a horizontal, tandem, compound Corliss engine (size 18x28x42 inches; horse power, half) are segregated below:

	Total Cost.	Per cent. Total Cost.
Cost in New York.....	\$3,335 80	61.70
Commissions.....	162 00	3.10
Freight, prime, insurance.....	558 02	6.80
Port Elizabeth charges.....	65 85	1.20
Railway charges, Port Elizabeth to Bulawayo.....	1,883 84	26.30
Receiving and forwarding.....	33 39	0.62
Total cost F. O. R. Bulawayo.....	\$5,339 90	

The improved conditions obtaining at the present time, in respect to ocean transport, railage and local handling, as well as a favorable fluctuation in the initial cost of plant, makes it possible to keep within these figures.

**ASSAY PLANS.**—Upon most of those mines which

have reached an advanced stage of development, surface and assay plans, as well as sections and stoping plans are kept. While the data embodied in these plans vary somewhat on individual mines, the fundamental principles are adhered to.

The development as well as the stope samples are taken at distances of 5 feet apart, generally, (one being guided by local conditions in the selection) and are plotted weekly. The values are customarily shown in "red," and the width in inches in "black." All samples are taken over the actual reef width, which figures are adjusted to an assumed stoping width when calculating the possibilities of the mine.

In the opinion of the writer, the method often used (in instances where width of reef is under an assumed stoping width) of sampling beyond this stoping width, including both reef and country matter, is liable to produce very inaccurate results. It appears clear where the character and hardness of the rock and mineralized matter show a marked difference, it is almost impossible to obtain the proportions of each section necessary to insure reliable results. These remarks are particularly applicable to this country where so many narrow but highly auriferous veins occur, which have in many cases lent themselves more readily to oxidation than the adjoining rocks.

Sectional sampling is resorted to extensively, not only in development work, but in all stope breasts, in order to avoid as far as possible the handling of ore which will not leave a margin over and above the cost of mining and milling expenses. In this country the unit of value is the "dwt.," equal to \$1.03. In order that immediate approximations may be made of the stope breasts, daily stope samples are taken and panned, which after one has become familiar with the character of the gold and other conditions, furnishes very satisfactory results. All results plotted refer to fire assays.

In order to avoid, as far as possible, inaccuracies in plotting the stope measurements, the writer prefers to have the individual stopes drawn to large scale upon separate blocks, and these are used for calculating tonnages, etc. The scales used for underground general plans vary from 20 feet to an inch to 60 feet to an inch, depending upon the extent of the property.

**DEVELOPMENT WORK.**—Generally speaking, the quartz veins occurring in this country may be said to be narrow. The lateral continuity varies greatly, but in rare instances does it extend over the full length of a block—1500 feet. The grade (when the widths are adjusted to a common basis and suitable areas are used in the calculation) varies upon working propositions from 8 dwts. per ton to 22 dwts. per ton.

At the Wanderer mine, where a dry-crushing plant of about 300 tons capacity per day has recently been erected, the grade of ore being dealt with is stated to be under 5 dwts. per ton. In this case no underground work is necessary at present, the ore being quarried at small expense.

In common with other countries, when the industry is just emerging from infancy, Rhodesian ventures have suffered to that extent which is produced by the erection of reduction plants when there has been only a limited amount of development work accomplished, a mistake which is presumably made through an intense desire to record an output.

Usually at this stage in any country the conditions are abnormal, and if there is a period in the history of the industry which demands careful and cautious work it is at this time. However, where such large sums of money are required, as is the case in this country, the financial considerations are of first im-

Sample Grinder, Open.

Laboratory Roll Jaw Crusher, Open.

portance, and it appears to be necessary to take greater risks than in most other countries.

The period consumed in reaching the milling stage varies with the width and lateral extent of the vein being dealt with, but may be said to absorb from three to four years from the date that work is seriously undertaken.

The comparative cost of unskilled labor would suggest to those who are unfamiliar with other conditions that the expense of development work should be small. This is not the case, however, for, although the native wage may appear to be low, when the other expenses incident to their employment are considered, it is found that this account represents about 30% of the total cost of the work.

This condition is not clearly reflected in the figures given below, as the bulk of the work is accomplished under the contract system in that case.

The cost of stores, mining material, administration and many other incidental charges associated with mining operations in this country is very high. It is therefore essential that very large footages be obtained over stated periods, in order that reasonable distributions may be made of the "constants," observing that a large footage reflects favorably in the "cost per foot."

An analysis of the cost of development upon one of the properties with which the writer is connected is given below:

MINE DEVELOPMENT.			
	Total Cost.	Cost Per Ton Milled, Cts.	Total Cost, %.
Salaries.....	\$ 1,709 90	.044	2.47
White wages.....	3,538 88	.068	3.83
Contractors.....	22,110 67	.579	82.03
Native wages.....	3,885 49	.083	4.15
Native food.....	1,091 25	.028	1.58
Stores.....	2,693 96	.070	3.90
Maintenance.....	767 40	.020	1.11
Workshops.....	1,057 76	.027	1.53
Native hospital.....	290 12	.007	.42
Native labor supply.....	75 17	.001	.10
Pumping (underground).....	4,453 75	.116	6.50
Compound expenses.....	873 08	.022	1.27
Compressor and drills expense.....	16,570 56	.433	24.00
Hauling.....	1,621 67	.042	2.35
Underground tramming.....	2,750 95	.071	3.99
Manufacturing and sharpening rock drills.....	5,637 29	.146	8.18
Assay account.....	698 12	.018	1.01
Surveying and sampling.....	720 11	.018	1.04
Totals.....	\$99,176 01	\$1 80	

The footage executed over the above period was 2766 feet, representing a cost per foot of \$25 03, although if individual months when a full supply of labor was available should have been segregated a decrease in the cost per foot of about \$4.50 could be shown.

The tonnage dealt with over the above period was 38,054. The footages executed over given periods in this country are fair, although not to be compared with those obtained on the Rand fields, where I dare say greater progress is made than in any other mining country in the world.

With hand labor, driving in ordinarily hard ground, 40 feet per month is considered to be good work, while with machine drills 80 feet per month is a good average. On the Rand anything up to 200 feet per month is made in driving, while in shaft sinking the same footage is often executed.

Upon one property, with which the writer was connected some six years ago, no less than 260 feet of sinking was accomplished during one month of twenty-eight days, i. e., from the 1027-foot level to the 1287-foot level; at the same time ten drives were being extended from the shaft, the average footage in this latter work having been at the rate of 147 feet per month. The dimensions of the shaft were 17x7 feet.

The smaller amount of work obtained in this country is due very largely to inferior equipment, both underground and upon the surface, hence the rapid handling of large quantities of broken rock is in most cases impossible.

**WORKING EXPENSES.**—I believe that in Rhodesia the requirements of an engineer in respect to the number of properties he is expected to effectively handle are in excess of most countries. It is therefore necessary that detailed and complete records be kept of the work. The comparatively high and constantly fluctuating prices of mining material and supplies make it essential that constant quotations of these articles be obtained and filed for daily reference if any hope be entertained of effecting economy in operating expenses, as well as for the purpose of producing estimates which can be treated with confidence. The writer has in operation a system which, although appearing somewhat elaborate and entailing a good deal of secretarial work at the end of each month, is calculated to supply almost at a glance all of the information covering the month's work. The fluctuation in the operating expenses is clearly reflected and the factors which contribute towards these conditions are at once determined.

It is interesting to observe what an important bearing a fluctuation in the monthly tonnage handled has upon the operating expenses.

The foregoing remarks forcibly suggest the importance of correctly measuring the tonnages handled. In Rhodesia the methods obtaining in dealing with tonnages are not conducive to accurate results. The cars of certain calculated capacity are counted as they are delivered to the mill or crusher station, and this figure, less the number of cars which are discarded as waste (in all cases estimating

20 cubic feet to the ton), is calculated to be the tonnage crushed. This system is at fault, and it will be necessary to observe greater care in measuring the tonnages before a comprehensive comparison can be made between theoretical and actual results.

The above methods would be all right if, after determining the number of cubic feet to the ton in individual cases, each car delivered to the mill was filled to the same point and moisture samples were taken periodically. This, however, is almost impossible, at least, in this country. The stope measurements are, of course, used as a check, but it is hardly necessary to state that in either case only a very approximate result is obtained. This question is of so much importance, both as regards relative working costs, as well as relative stamp duty, as to suggest the adoption of a uniform and accurate method of measurement, at least in cases where the figures are to be filed for record or general information.

Scales should be used which automatically weigh and register the cars delivered. Then if each car be tared, and periodic moistures taken, a correct record of the tonnage handled would be obtained.

An analysis of the working expenses extending over a period of twelve months upon one of the properties with which the writer is concerned is given below, and it is intended that the points to which attention should be directed in order to effect economy will be reflected therein.

MINING.			
The tonnage mined during the above period was 44,011 and the tonnage milled amounted to 38,054:			
	Total Cost.	Cost Per Ton Milled, Cts.	Total Cost, %.

## Wolfram, and How to Know It.

Written by B. DUNSTAN, Government Geologist, Queensland.

As wolfram is so much in demand at the present time, and inquiries are being constantly made as to its mineralogical characters, the following notes may prove useful to the prospective wolfram miner:

The physical characters of wolfram—color, luster, streak, specific gravity, cleavage, etc.—are all aids in recognizing it, and the wolfram prospector should be familiar with those characters, while he should also possess a knowledge of such other of its properties as can be readily tested by a miner in the bush. In addition to this, he should know the more common minerals mistaken for wolfram, and how to distinguish that mineral from them.

Wolfram is of a black or deep brownish-black color, and has a luster somewhat resembling black glass, but with a metallic or submetallic tinge. In breaking, it usually cleaves along flat, shining faces very much like antimony, and in this respect is very different from the conchoidal (or shell-like) fracture of broken glass. Where exposed on the surface this cleavage is not always present.

In handling the mineral, one is impressed with its heavy "weight"—or, more correctly speaking, its "specific gravity"—being much heavier than iron, not quite so heavy as lead, and about the weight of metallic copper.

The following list shows the specific gravity of wolfram compared to that of other substances: Wolfram, 7 to 8; magnetite, 5; hematite, 5; hornblende, 3; tourmaline, 3; titanite, 5; tinstone, 7; rutile, 4; glass, 3; metallic iron, 7; metallic copper, 8; metallic lead, 11; and water (the standard), 1. Water is used as the standard by which the specific gravity of minerals is estimated—the weight of a mineral compared to that of an equal bulk of water being its specific gravity—so that wolfram is between seven to eight times heavier than water, or roughly, half as heavy again as hematite.

The "streak" is the mark left when a mineral

is scratched by a substance harder than itself, and corresponds to the "powder" produced when the mineral is finely crushed. Minerals agreeing with one another in color very rarely have the same streak or powder, and this fact is useful in distinguishing wolfram from those minerals which otherwise it closely resembles. Magnetite, hematite, titanite, manganese-dioxide, tourmaline, tinstone, hornblende, zinc blende, chromite, black volcanic glass and coal are all black—or most of their varieties are—but vary considerably in the color of their "streak." The streak of magnetite, coal and manganese is black; that of tourmaline, tinstone, rutile, hornblende and volcanic glass is of various shades, but all light colored; while hematite, zinc blende, chromite and titanite iron more or less resemble that of wolfram in having a dark-colored streak tinged with brown or red, or having an admixture of these colors.

The "hardness" of a mineral is also a very useful test, and is usually determined by means of a file or hard-tempered knife blade. One mineral of known hardness may be employed to test the hardness of others not known, but it is found that, for testing common minerals, the ordinary knife blade answers most purposes. Titanite, iron, chromite, wolfram, hornblende and volcanic glass are about as hard as a common knife blade, while hematite, tourmaline, magnetite, tinstone, rutile and franklinite are all harder. Manganese ores vary so much that this test, in the hands of a novice, becomes unreliable. The hardness of wolfram varies from 5 to 5½; hematite, magnetite, franklinite and rutile are about 6; titanite, iron, between 5 and 6; zinc blende, 4; chromite, 5½; volcanic glass, 3; window glass, 4½; a file, 6½; copper coin, 4; soft copper, 3; common knife blade, 5; hard tempered knife blade, 6½.

In the absence of a mineralogist's blowpipe, a blacksmith's forge may be utilized for testing another property of the mineral. When heated without any flux, hematite, tinstone, rutile, franklinite, magnetite, chromite, zinc blende and titanite iron are infusible, or nearly so; tourmaline, hornblende, volcanic glass and wolfram are fusible; while coal—except the anthracite variety—will easily burn away.

As an example of the working out of the various tests, a blackish mineral is taken. Its weight at once impresses the observer, and a rough estimate shows it to be abnormally heavy. It would therefore not be hornblende, chromite, zinc blende, tourmaline, rutile or volcanic glass, but might be either wolfram, magnetite, hematite, titanite iron or tinstone. (Specific gravity test.)

A piece is very finely crushed with a hammer or rubbed with a file, but gives a "powder" or "streak" which is neither black nor light colored. Taking those among which the mineral might be found in the previous tests, it will be seen that it cannot be tinstone (light colored) or magnetite (black), but, being reddish or brownish, may be wolfram, hematite or titanite iron. (Streak test.)

A small chip of the mineral is next tested in a blowpipe flame, or a larger piece in a forge fire, and the mineral fuses or melts on the edges or corners; it is therefore not hematite or titanite iron, and is probably wolfram. (Fusibility test.)

A flake is broken from a sample and the clean, bright submetallic luster on a cleavage face is shown—the presence of the mineral is confirmed. (Cleavage and luster tests.) The order of all these tests may be varied according to circumstances.

A few remarks concerning tungstic ochre and scheelite, two other tungsten minerals, might be appropriate. Like wolfram, they contain a very high percentage of tungstic acid, and the wolfram miner should be on the lookout for them.

Tungstic ochre is an earthy mineral of a yellowish or greenish-yellow color, and results from the surface decomposition of wolfram. Scheelite is a whitish or yellowish-white mineral, about as hard as a common knifeblade (hardness = 5), is not as heavy as metallic iron or wolfram (specific gravity = 6), and frequently occurs with the latter mineral.

The minerals likely to be mistaken for scheelite are cerussite (carbonate of lead), anglesite (sulphate of lead), pyromorphite (phosphate of lead), barytes (sulphate of barium) and witherite (carbonate of barium).

Witherite and the three lead-bearing minerals—cerussite, anglesite and pyromorphite—are all fusible when heated alone in a blowpipe flame or in a blacksmith's forge, provided small pieces are used. If heated with bicarbonate of soda, in the proportion of 1 of mineral to 4 of soda, they can be reduced to metallic lead, while scheelite and barytes are only fusible with some difficulty and give no metal. Witherite and barytes contain the element barium, and in consequence give a greenish color to a flame when intensely heated alone.

Barytes and witherite may easily be distinguished from scheelite—first, by the color they impart to the flame, as indicated above; second, in being lighter in weight (scheelite = 6, barytes and witherite = 4½); third, in being softer (scheelite = 3½, barytes and witherite = 5); and, fourth, in having no connection with wolfram. The three lead minerals are associated with galena, although on the surface of an outcrop the latter mineral may not be present.

White arsenic is a rather heavy mineral, but not so heavy as scheelite (specific gravity = 3½), is soft

(hardness = 2 or less), makes white fumes having an unpleasant odor when heated in a fire or with a blow-pipe, and is usually associated with mispickel the whitish, metallic arsenical pyrites.

Antimony oxide (cervantite) is whitish or yellowish, has a specific gravity of about 4, a hardness of about 4, is infusible and is always associated with the metallic antimony ore (stibnite).

The above may be some guide to the wolfram prospector, but it would be very desirable, although impracticable, to put into the hands of every one supplied with this information small pieces of these minerals for reference, if only the size of a marble, and also pieces of the other minerals for which they might be mistaken. With the addition of a blowpipe, an ounce of bicarbonate of soda, a piece of candle, a pair of forceps, a block of charcoal, an elementary book on minerals, and a reminder at the start not to "know all about it," the prospector's testing outfit would be complete.

## Mining and Metallurgical Patents.

PATENTS ISSUED FEBRUARY 7, 1905.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

PROCESS OF PRODUCING PURE COPPER.—No. 782,145; L. M. Lafontaine, Paris, France.

Process for refining copper by forming copper producing substances into plates, inserting plates with suitable cathode plates into electrolytic bath, which has previously been prepared by saturating water with sulphate of copper, then adding to same a quantity of sulphuric acid, then filtering liquid and adding calcined soot thereto, and directing current of electricity through cell thus formed.

ORE CONCENTRATOR.—No. 782,078; A. H. Stebbins, Little Rock, Ark.

In concentrator, combination of frame, concentrating surface supported by frame, series of concentrate guides disposed diagonally over concentrate surface, series of tailing guides disposed above concentrate guides, concentrate and tailing guides being arranged at angle to each other, concentrating surface being formed of sheet material having perforations therein, walls of which are offset to direct fluid currents over or parallel to surface.

APPARATUS FOR ANHYDROUSLY CONCENTRATING ORES OR THE LIKE.—No. 782,118; G. H. Fettus, Philadelphia, Pa.

In apparatus of character recited, combination of horizontally revoluble drum, provided with conical end portions, and central cylindrical portion, interior and exterior communicating pockets, forming periphery of cylindrical portion of drum, together with means for supplying material to exterior pockets in ascent of rotation.

APPARATUS FOR RAISING LIQUIDS FROM DEEP DRILLED WELLS.—No. 782,040; T. F. Moran, De Young, and F. J. Moser, Kane, Pa.

In apparatus of character described, combination of casing provided with partition separating same into upper and lower compartments, tubular member connected with partition and provided with apertures disposed below same, air-pipe provided with packings engaging tubular member and apertures disposed intermediate of packings, apertures of air-pipe being disposed adjacent to apertures of tubular member, conductor pipe in communication with upper compartment and extending into lower compartment to point adjacent to bottom thereof, and means for preventing retrogression of liquid from upper compartment to lower compartment.

METHOD OF MATTE OR PYRITIC SMELTING.—No. 782,123; O. S. Garretson, Buffalo, N. Y.

Method of matte or pyritic smelting which consists in bessemerizing or converting matte by blast underneath column of material containing flux, maintaining flow of resulting slag to forehearth, supplying sulphur bearing material to slag in forehearth, while maintaining slag in freely flowing condition, thereby producing low grade matte which combines with metal or matte contained in slag, and maintaining

flow of such low grade matte back to bessemerizing or converting region.

ROTARY ORE ROASTING FURNACE.—No. 781,824; F. Heberlein, London, and W. Hommel, Lee, England.

Rotary muffle furnace for roasting ores, comprising ore chamber floor of which rotates, heating chamber immediately beneath, rotating with floor of ore chamber, and stationary heating chamber immediately above ore chamber; heating gases being caused to circulate first through lower heating chamber and subsequently through upper one.

METALLURGICAL FURNACE.—No. 781,834; R. L. Lloyd and P. Thill, Greatfalls, Mont.

In metallurgical furnace, stationary longitudinally curved hearth for ore, in combination with ore feeding mechanism disposed in space between turns of hearth.

FURNACE OR KILN FOR ROASTING ORES.—No. 781,904; G. O. Petersson, Dalsbruk, Russia.

Furnace or kiln for roasting finely crushed ore, burning dolomite, etc., provided with flat arches b, c, d arranged in shaft at different levels zigzag with reference to one another, and having space between themselves and walls of shaft and with space beneath bottom arch or arches b communicating at one end with outer air and at the other end with fire chamber which in its turn communicates with one end of space beneath arch or arches c above, while other end of latter space is in communication with chamber h, in its turn communicating with space beneath top arch or arches d, space last mentioned communicating with chimney either directly or through aid of other arches compelling gases to flow repeatedly back and forth in furnace or kiln.

## MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

(Special Correspondence).—The approximate copper production during 1904 was 206,000,000 pounds for Michigan and 204,000,000 pounds for Arizona, there being a gain during 1904 of about 15,000,000 pounds for Michigan and nearly 60,000,000 pounds for Arizona. Utah produced upwards of 50,000,000 pounds last year, almost exclusively from Bingham, in Salt Lake county. Montana also made a small gain, but no great increase is to be looked for from the Butte camp. Montana's prospects of future increase depend mainly upon developments in the new Corbin district of Jefferson county, where there is considerable activity and where there are several new properties of promise. In California there was an increased production, due to better conditions at the property of the Mountain Copper Co., in Shasta county. The Bully Hill mine, near the Mountain, also was a small producer. The Wyoming output during 1904 was very small. Washington and Oregon both made a little copper, but have not as yet opened important producing mines. South Dakota's production was confined to a few hundred thousand pounds, secured mainly in low-grade fluxing ores. Colorado secured between 6,000,000 and 10,000,000 pounds of copper yearly from cupriferous silver, lead and zinc ores. The plans of the Calumet & Hecla, at Lake Superior, call for the installation of one of the largest electric power plants ever constructed. The favorable developments on the Kearsarge lode in the two shafts of the Calumet & Hecla have directed attention to the Tecumseh, lying next south of the Osceola, which, in turn, is the southern neighbor of the Calumet & Hecla. The Tecumseh sunk two deep shafts—one on the Calumet conglomerate and one on the Osceola amygdaloid—without finding enough copper to render the shafts even fairly promising at any single point.

Houghton, Mich., Feb. 14.

### ALASKA.

(Special Correspondence).—The Klondike & Boston G. M. Co. has put in a complete hydraulic plant on Grubstake gulch at Willow Creek, and is the first and the only operator in the Sushetna valley, and will also install a Ruble elevator on Willow creek next season. Willow Creek, Feb. 11.

At present the coal production of Alaska is limited to a few thousand tons used for local purposes; but some of the coal-bearing areas promise well. It is reported that the Admiralty Island coal fields, in southeastern Alaska, have been practically abandoned. At one time the evidence of good lignite was promising. On the Bering river, 300 miles west of the Admiralty islands, near Controller bay, commercial veins of semi-anthracite coal have been found, resembling the harder bituminous coals of the eastern United States. Considerable work has been done at Homer, on Kachemak bay, in the Cook Inlet region. The Alaska Packers' Association get about 600 tons annually of lignite from near Chignik bay. In the northeastern part of the Seward Peninsula, on Chicago creek, a tributary of the Immachuk river, some good coal has been mined. Coal mining on the Yukon received a check when the river steamers put in oil burners. The Cape Lishurne coal fields, 300 miles north of Nome, have produced considerable coal, which has been sold at Nome for \$18 and \$20 a ton in competition with Comax and Washington coal. In 1903 less than fifty tons were sold to whalers.

In the Norton hay region evidences of coal have been found in narrow belts in Tertiary sediments on the Tubutulik and Koyuk rivers. In northern Alaska, in the Dall river region, a firm, bright lignite has been found in soft gray shales outcropping in the bed of Coal creek, 1 mile above the Dall river. An impure lignite is found along the banks of the Kowak between the mouths of Squirrel and Reed rivers, and it is probable that they occur in the lower valleys of the Reed, Salmon and Hunt rivers.

In the Mt. Wrangell district coal has been found near the head of the Chesna as a glossy lignite with conchoidal fracture in soft buff shales. It has been used by Slate creek miners for blacksmithing. Also, along the bluffs of Slate creek, below the mouth of Miller gulch, coal has been found which was used for the same purpose. Prospectors report considerable coal on White river, between the head of the Attul and the mouth of the Donjek. Coal has also been found on the Chesnina, Tazlina and Chitstone rivers, the latter being a dark-gray coal having many of the characteristics of cannel.

### ARIZONA.

#### Cochise County.

(Special Correspondence).—The Copper Queen M. Co. at Bisbee has resumed work on ground which has been lying idle since the fall in the price of silver. The Copper Queen formerly worked ore bodies which carried silver running as high as 700 ounces to the ton, but when silver fell these ores were left standing.

Bisbee, Feb. 14.

(Special Correspondence).—The shaft at the Leadville property, near Turquoise, is down 300 feet, a gasoline hoist having been used in the work. Drifts have now been started from the station and will be run south and west. A body of sulphide ore was run through during the last 100 feet of the shaft. A. J. Houle is in charge. The company has been incorporated as the Michizona M. Co.

Turquoise, Feb. 13.

It is reported that the management of the Calumet & Arizona, the Calumet & Pittsburg, the Lake Superior & Pittsburg, and the Pittsburg & Duluth M. Cos. and the Junction Development Co. at Bisbee have determined upon a consolidation. The capitalization under the reorganization and consolidation will be \$32,000,000. The

companies named have from the beginning been practically under the management of the Calumet & Arizona, being the parent of the other organizations. This mine has paid several millions in dividends since reaching the producing stage a few years ago, and has gathered a surplus of nearly two and a half millions. Its smelter is at present turning out at the rate of 350,000 tons of copper a year. An increase to double this capacity is expected during the year. Of the other properties none are as yet producing, although the Lake Superior, the Calumet & Pittsburg and the Pittsburg & Duluth are about ready to do so, having large ore bodies blocked out. With their coming in large expenditures will be necessary for reduction works and other equipments. The present joint capitalization of the companies aggregates about \$50,000,000. The new capitalization is thus a reduction. The stocks of the companies outstanding will be taken in the stock of the new organization issued at ratios of value which will fully protect all the present holders.

#### Maricopa County.

(Special Correspondence).—The Mormon Girl mill, in Cave Creek district, is closed down for a short time, as all roads to the mines are washed out and it is impossible to supply the mill with ore until repairs are made.

—The Oriental M. & M. Co. is installing machinery on its property in Cave Creek district.

Phoenix, Feb. 14.

#### Pinal County.

(Special Correspondence).—The new double-compartment shaft being sunk by the Troy-Manhattan Co. on the Buckeye vein, near the smelter ore bins, is 200 feet deep. The work of opening the levels to the east and west along the vein from the bottom of the shaft is progressing rapidly and the results are satisfactory. A large warehouse and a change house are being built on the main shaft dump. The management intends to put in a smelting plant of 100 tons capacity per day. The Buckeye ore when mixed with ore from the sulphide bed in the Rattler mine is self-fluxing. Thomas Kavanaugh is superintendent at Troy. J. W. Sisson is president.

—The test run of the Saddle Mountain M. Co. was a success. A 30-ton jacket was fitted up to make a five days' run. The ore proved to be self-fluxing and smelted so freely as to require from 50 to 60 tons of ore per day to keep the furnace running. After the test run was completed the old 30-ton jacket was taken down and is now being replaced by a new 150-ton jacket, which, owing to the excellent smelting qualities of the ore, will probably handle over 200 tons per day. G. B. Chittenden is the general manager at Dudleyville. This property lies at the eastern end of the Dripping Springs range, 15 miles from Troy.

Troy, Feb. 15.

(Special Correspondence).—It is reported that oil has been struck in a well that is being drilled on the San Pedro river, above Mammoth.

Mammoth, Feb. 13.

S. Burger of Salem, Mass., has contracted with A. C. Sheldon and A. G. Wilson for the Copper Peak group of mines, on the Gila river, 20 miles east of Florence. It is understood that they propose to thoroughly develop and equip the property in which they have become interested.

#### Yavapai County.

(Special Correspondence).—While the Poland M. Co. at Poland is unable to run its mill on account of the recent burning of the Val Verde smelter, which was treating its concentrates, active work is in progress in the mines. The drift from the tunnel on the Poland ledge is in about 2500 feet, and in going this distance good ore bodies have been encountered. A drift is also being run on the Accidental ledge on the Lynx creek side of the mountain from the tunnel, and a body of good ore has been encountered in it, as also on the C. O. D. ledge, which is near the Accidental. The drift on the Accidental, at the tunnel level, is from 840 to 850 feet deep.

Poland, Feb. 13.

(Special Correspondence).—Although recently published lists of Arizona's dividend paying mines place the United Verde at Jerome fifth, in reality it heads the list. Up to the present time it has paid a total of \$16,860,322, and for the year 1904 alone paid out in dividends \$1,800,000. The Arizona Copper Co. has paid total dividends of \$5,489,503; the Crowned King, Yavapai county, \$242,760; La Fortuna, Yuma county, has a record of \$1,062,500 paid in dividends; the Pride of the West paid its last dividend in 1901 at the rate of 3 cents per share. The total showing in dividends from the Standard Copper Co. is \$40,000, the last payment, 50 cents on the share, being made in 1903. Mines still paying big dividends are: The Copper Queen, Calumet & Hecla, Boston & Montana, Amalgamated, Anaconda, Calumet & Arizona and the King of Arizona. In another few months the United Verde will be one of the best mines for the miner to work in that there is in the Territory. Under the present management the mine is being brought into perfect ventilation and safety so far as cave-ins, etc., are concerned, and this mine bids fair soon to attract miners instead of, as in the past, being shunned by them.

The Pittsburg-Jerome M. Co. has located in the Jerome mining district, 2 miles south of Senator Clark's great United Verde mine, and the same distance north of the Copper Chief and Senator Clark's Equator mine, a producer located on Equator hill, is doing active development work.

Jerome, Feb. 14.

(Special Correspondence).—There are more men at Cherry Creek than ever before, and the forces on almost all the properties are being increased. At the Pfau the reduction works is being rapidly completed. At this mine the laborers are chiefly Americans—an unusual condition in Arizona, where Mexicans form a large percentage of the mine workers. The Gold Lode Co. recently purchased the Sessions ranch, which takes in the valley 1½ mile below the mines and has an ample supply of water for all purposes, also furnishing a good location for reduction works. The Gold Lode shaft is down 200 feet. The main tunnel on the Bugler has reached a length of 350 feet. An upraise from this to an upper tunnel, a distance of 130 feet, is all in ore. A winze is sunk in this lower Bugler tunnel at a point 245

feet in and has followed the vein down, being in high-grade ore.

Cherry Creek, Feb. 14.

D. C. Thorne of Prescott, interested in the Arizona G. M. & M. Co., in Santa Maria district, proposes to put in a dry crusher system of rolls and a 50-ton cyaniding plant. — A hoist, air compressor and other machinery has been ordered for the properties of the Baumann Copper Co. on the Agua Fria.

#### Yuma County.

H. J. Beemer of the Amalgamated Gold Co. is supervising the erection of a 60-stamp mill at Quartzsite, 100 miles from Martinez, the nearest railroad station. The company has a driller and will put down a hole 5000 feet, if necessary, to develop water. An electric motor train will be used to haul machinery and supplies from Martinez to the camp. The generator for this train weighs ten tons and is equipped with 90 H. P. engines and 75 H. P. generating motors. The cars weigh 4½ tons and have 3½ H. P. motors. On a good road fifteen tons to the car is a load. The speed is about 5 miles per hour, and when working full capacity about eight gallons of gasoline or distillate is used per hour. The water from the engines is thrown onto a netting and cooled by an electric fan and reused.

### CALIFORNIA.

#### Butte County.

The California State Mining Bureau reports the mineral production of Butte county for 1903:

	Quantity.	Value.
Brick, thousand	1,200	\$ 7,200
Gold	1571	1571
Lime, barrels	250	250
Limestone, tons	190	250
Mineral Water, gallons	13,000	1,550
Platinum	210	210
Silver	358	358
Total		\$1,581,825

The Gold Garden M. Co. is building a dredger on their land, near Wyandotte.

#### Calaveras County.

The '49 mine at Douglas Flat has been leased to a company who have placed W. Moyle of Vallecito in charge of the underground works.

#### El Dorado County.

W. J. Dingee, proprietor of the Eureka Slate Quarries at Slatington, will let contracts to clear a large tract of land to the north of the pit through which the main belt is known to pass. To expedite this part of the work the present force is to be doubled and an engine and dirt train will be pressed into service. It is estimated that the projected improvements when completed will more than double the present output of the quarries and even then they will have to be run to their full capacity in order to supply the present demand for slate.

#### Inyo County.

M. T. Stovall of Bishop states that work will be resumed on the Bishop Creek G. Co.'s mines as soon as the weather permits. — M. Jungheidel intends to build a sampling mill near Bishop in the spring. — The Mount Whitney mines, near Lone Pine, are stated to have lately uncovered an encouraging body of rich ore. A townsit, to be called Mount Whitney, is being surveyed by the company 1½ mile northwest of Lone Pine.

#### Nevada County.

P. Deidesheimer has a bond on the Morning Star quartz claim, near Cherokee, from J. Curnow, and will develop it and its extension on the Badger Hill ground.

The California-Grass Valley G. M. Co. will work the Chicago mine, near Grass Valley. D. E. Morgan is president; C. C. Haub, vice-president; G. H. Tuttle, secretary and business manager; W. P. Martin, superintendent. Last October the company took up the Chicago and has since cleaned out the old tunnel, run 800 feet of drifts and completed an air shaft 150 feet long. The company intends to build a mill and all the necessary machinery during the coming summer, all of which will be operated by water power. All the water necessary will be obtained at a very low rate, as it is turned back into the South Yuba ditch after being used. Water will be piped from the upper ditch to the mill, where it will have a head of 143 feet. Thence it will be carried to the lower ditch and liberated.

#### Placer County.

S. N. Dutchess of Newberry, Mich., owning the Alameda mine at Black Canyon, has let a contract to F. W. Snyder to run the main tunnel north and will start the mine about the middle of May. The shaft is 160 feet deep. The mine is equipped with a 20-stamp mill and concentrators, run by steam power.

The X Ray mine, in Sailor canyon, has been handed to G. E. Ward of Santa Cruz. He has four men at work driving a tunnel to tap the channel. J. H. Sunley is in charge.

#### San Bernardino County.

The Gold Park Consolidated Mines has been organized in Los Angeles to operate fifty-two claims in the Gold Park district of Riverside and San Bernardino counties. The company is planning to install a pumping plant on water lands recently secured and to build a pipe line 7 miles long to the mines. A mill is to be built on the ground. W. E. Winnie is president, D. D. Whitney vice-president, J. E. Schweng secretary and J. N. White superintendent.

#### Shasta County.

The air compressor and other machinery at the Mammoth mine, near Kennett, is now run with electric power furnished by the Northern California Power Co., which has a substation at the smelter site, between the mine and Kennett.

#### Siskiyou County.

Placer mining is the most important of the resources of northern Siskiyou county. This season the rains have been late, but now many of the mines are being hydraulicked, though somewhat hampered by difficulty of access. — The Siskiyou mine, near Happy Camp, is being worked by W. J. Brown, with ten men. The plants are working constantly. — The Van Brunt mine is being worked by Superintendent Jackson, for Eastern capitalists, with fifteen men and two giants running night and

day.—The Minetta B mine at Nolton is being worked by Superintendent T. J. Nolton with ten men.—It is expected that the Classic Hill, north of Happy Camp, will build a road to Waldo, Or., so as to cheapen cost of supplies. The mine is being worked with ten men.—The Medina G. M. Co., operating the Carson & Kradle and Gardiner ledges at Oro Fino, have struck a rich pay shoot of ore in both tunnels and are taking out a high-grade rock. They have started their mill and expect to keep it running. The new compressor and Burleigh drill plant at the Johnson mine, operated by the same company, are in place ready for operation.—W. H. Young of the King Solomon mine, near Cecilville, reports that the ledge has been struck in the new 800-foot tunnel. The company may put in a milling and cyanide plant when the wagon road can be extended from Black Bear.

#### Tuolumne County.

Superintendent A. J. Crowell has started up the Densmore mine, near Columbia.—At the Brindle Pup claim, near the Densmore, six men are at work. A steam hoist has been put in. W. G. Cole is foreman.—At the Dana mine, on Gold hill, B. C. Smith will commence operations with a hydraulic ram.—At the Now Calico mine, northeast of the Jumper mine, Stent, H. B. Parker states that a mill is to be built. Sufficient ore is blocked out in the mine to keep ten stamps busy for two years. G. H. Gerken is superintendent.—At the Republican mine, near Jacksonville, they are running three development drifts and two prospect crosscuts on the 500 and 650 levels. A new Dow duplex pump has been installed at the 650 level to handle the water. The 20-stamp mill is running steadily.

Work has been discontinued at the Dreisam, near Carthers, and F. A. Baier will do some drifting on the Good Luck this spring.—The Big Oak Flat claim, near Big Oak Flat, has been sold to the Monterey M. Co. by J. L. D. Roberts, T. A. Mitchell and J. F. Moore.

#### Yuba County.

F. K. Lord of Camptown, who recently located several miles of Canyon creek in the interest of a San Francisco company, will have a black sand plant erected in the spring to work the sand.

The old Council Hill mine, near Brandy City, is being worked by W. Reid.

### COLORADO.

(Special Correspondence).—For some time past traffic on the mountain railroads has been seriously impeded and, in some instances, entirely abandoned, on account of snowslides and heavy storms which have been raging in the mountains. The eight-hour bill, which is before the Legislature now in session, has been amended in such a manner that, if it becomes a law as amended, it will afford relief to but small proportion of the laboring class. The object of the bill as originally introduced is to grant relief to the smeltermen as well as the underground workers. The bill as originally introduced has met with strong opposition, and it is doubtful if any eight-hour measure is passed at this session of the Legislature.

Denver, Feb. 11.

#### Clear Creek County

J. Peterson of Clifton, Ia., and J. May of Cincinnati, O., president and secretary of the Golden Cloud M. Co., operating the Golden Cloud mine at the head of Virginia canyon, near Idaho Springs, may build a mill on their property.

The Corry M. Co., at Silver Plume, has taken a bond on the Wisconsin mine on Sherman mountain, thus averting litigation, as the owners of the Wisconsin had filed damage suits for \$100,000 against the Corry Co. C. S. Desch is superintendent.—Good progress is being made in putting up the framework of the Dives-Pelican mill at the Burleigh tunnel and it will soon be ready for machinery. The old air compressor formerly in use at the tunnel has been taken out to make room for the new boilers which will be installed to supply steam for the new compressor, and which are expected to arrive in a short time. The air pipe line which supplied the upper workings of the Pelican is being taken down so that the pipe can be used in other places. The crosscut being driven from the Burleigh tunnel to cut the Pelican and other lodes at that depth is being pushed as rapidly as possible in order to make connections. The company is spending a large amount of money in putting this property in shape for a greater ore production, and after the mill is in operation and the contemplated development work carried out the output of ore will be much larger than it has been for many years.

#### Eagle County.

The Spirit mine, adjoining the Iron Mask, at Gilman, is ready to receive the machinery. One stope of manganese is reported to be 300 feet long, without side, top or bottom as yet discovered. This will be marketed, while a force of miners is employed exploiting the second contact—the sulphide and the overtopping carbonates. W. F. Deaver of Leadville is the prime mover in the enterprise and W. W. Buell is superintendent.

#### Gilpin County.

The Penobscot M. & M. Co. is driving its tunnel from Gambell gulch, the main tunnel being 1436 feet. Manager P. J. Hamble says that the company may build a mill to treat its own product, but the matter will be delayed for some time in order to determine the real character of the ores in the property and the best process for treating them.

#### Gunnison County.

It is reported that G. Farnham will build a mill to treat an auriferous hematite ore recently discovered on the Niagara claim, in McIntyre gulch, near Ohio City.

The Taylor Park M. Co., T. T. Goodale, Boston, Mass., managing director, is working 8 miles south from Cooper's camp, near Dorchester. Local Manager A. E. Smith is employing thirty men and is shipping high-grade ore. The property is developed by three tunnels. No. 1 cuts the vein at a point near the outcrop. No. 2 cuts the vein 600 feet deeper and it is from a winze in this tunnel that the high-grade ore is being shipped. The values are in silver, gold and lead. No. 3 tunnel, which is now in over 3000 feet, will cut the high-grade vein in about ninety days at a depth of 900 feet below

tunnel No. 2. They have opened up an immense body of low-grade ore in this tunnel which will not bear the excessive transportation charges to ship out crude, as it costs \$18 per ton to take this ore from the mine to Denver and the smelting charges are \$8 per ton. When tests are completed showing the best method of treatment, a plant will be put in at the mine. There is sufficient water power on the ground to operate the plant. A telephone line has been constructed from the mine to Dorchester and will be extended to Aspen in the spring.—Superintendent Jensen of the Forest Hill mine, in Taylor Park, has a force of men breaking ore for the mill, which will start after the freezing weather is over.—Manager Erickson of the Climax property, at the head of Taylor river, will do considerable prospecting with a diamond drill in the spring.

#### Lake County.

(Special Correspondence).—At the Murphy shaft on the Iron Silver M. Co.'s ground on Rock hill, near Leadville, sunk by the Gnu Co., composed of W. G. Brown of Denver, M. Starnie, J. Harvey, Jr., and J. Murphy of Leadville, 368 feet from the surface, 20 feet of an ore shoot 6 feet wide has been opened up. The Iron Silver M. Co. is sinking a new shaft on the Dome, northeast of the Reindeer. Several lessees are sinking shafts to the south of the Reindeer.—The Rock Hill M. Co. leased and handed the Nil Desperandum, Robin Hood, Cornucopia, J. M. C. and Australasian claims. The old shaft on the Nil Desperandum is being sunk to the lower levels and drifting has been started to find the ore channel. C. S. Collins of Nashua, N. H.; E. A. Carter, L. F. Carr and W. G. Morse of Springfield, Mass., and S. Davis, J. H. Goodspeed and S. G. Collins of Boston, Mass., are interested.—The United M. & D. Co. of America has the south half of the Little Sister, Quig, Mike and George H. claims, 320 acres, and is sinking a shaft on the George H. claim. J. G. McNulty of Leadville is in charge.—F. H. Minard is sinking a shaft on the Parson, 1 mile southeast of the Little Sister borehole, to be sunk to the blue lime. Two other shafts are being planned to be started on the Owers land.—This territory on Rock hill has been prospected by boreholes and promises much for the prosperity of Leadville.

Leadville, Feb. 14.

#### Ouray County.

The deal whereby the Camp Bird Co. secured 51% of the Imogene G. M. Co. holdings, comprising eighty claims, means the driving of the crosscut tunnel of the Camp Bird 4500 feet farther in a direct line for the Imogene G. M. Co.'s tunnel in Spirit basin on the Red mountain side, which is now in 1500 feet. The contract is to be let upon the return from Chicago, Ill., of L. V. Jackson, general manager of the Imogene G. M. Co., for 1000 feet more of the same tunnel. The price paid by the Camp Bird Co. was \$400,000. Provision is being made by the Camp Bird Co. to handle the water they stand so much in need of, and which they expect to tap in the upper Imogene basin by the extension of the crosscut tunnel. There are 250 men working on the Camp Bird, and this force will be increased and work on the tunnel, both from the Camp Bird and Spirit basin sides of the range, will be pushed to completion.

The Belle Creole property in Eureka mining district, near the Sunny Side Extension, in Sunny Side Basin, has been sold to the Ross M. Co. of Pittsburgh, Pa., for \$100,000, by G. Howard of Howardsville.

#### San Juan County.

The Waldron M. Co., J. D. Bardwell manager, operating in the Mineral Point district, near Silverton, has sunk the Adelia shaft 200 feet deep and has commenced drifting both ways on the vein.

The Hamlet M. & M. Co. has started grading for its mill at Midland and for a track from the main road of the Silverton Northern Railway to the site of the mill. The new mill will consist of crusher, rolls, jigs and Wilfleys, and so constructed as to permit of additional units to the 50-ton plant, as requirements may become necessary with developments of ore bodies.

The first tube-mill plant in Colorado has been put in at the Gold King mill, near Silverton, consisting of four tube mills, 5 feet diameter by 14 feet long. These mills recrush the tailings from an 80-stamp mill to pass 50-mesh screen; pulp is then classified and reconcentrated on Wilfley slimers. This tailing plant has been in successful operation for two months.—The 300-ton plant for the Green Mountain M. & M. Co. is being stored away until spring. In the meantime, E. Walter is running intermediate levels, putting in upraises and blocking ore.

#### Summit County.

The Mineral Belt and Lucky mining properties on Mineral hill have been sold by S. B. Wright of Denver to the Beaver Creek G. M. Co., now operating in Buckskin gulch and on Silverheels in Park county. The Mineral Belt and Lucky consists of twelve lode claims and 2 millsites, on east slope of Mineral hill, 2½ miles from Breckenridge. The Lucky property has 3000 feet of tunnels and drifts and nearly 2000 feet of shafts. The longest tunnel is 1700 feet and cuts the four large veins extending through the hill. The main shaft is 600 feet and taps the extreme end of the tunnel to the mill. The other tunnel of 600 feet has already cut two of the veins and is nearing the third. The property is equipped with a concentrating mill of 50 tons capacity, pump and hoist. F. A. Yauger of Chicago is general manager and is preparing to begin work.—The Sallie Barbara, on Nigger hill, near the head of Australia gulch, has been sold by Wm. Robinson for \$10,000 to D. Gray and W. E. Bowden, Canon City and Leadville, who will put hoisting machinery on the property and operate it as a zinc-lead proposition. The old shaft is 270 feet in depth, and will be unwatered and the drifts put in shape for production.

#### Teller County.

The McKinney Extension G. M. Co. has twelve acres between the Anaconda and Mary McKinney near Cripple Creek, and will sink a shaft 300 feet. A hoist and air compressor are being put in by Manager J. Sharp.

The referees appointed by the United States District Court in Denver in the \$1,000,000 damage suit brought by the Morning Glory G. M. Co. against the Mary McKinney M. Co., for alleged illegal extraction of ore belonging to the plaintiff by right of apex, have filed their

findings in the United States court. Two of the referees find that the Mary McKinney Company owes the Morning Glory Company approximately \$64,000, while the third referee, in a minority report gives the plaintiff \$54,000. The plaintiff company brought suit to recover the value of ore taken by the Mary McKinney Company, which was claimed by right of apex to belong to the Aileen claim of the Morning Glory Company. Although \$1,000,000 damages was demanded, the plaintiff claimed that \$862,000 worth of ore had been extracted, while the defendant company claimed that only \$25,000 to \$35,000 worth of ore belonging to the Aileen claim had been extracted. The referee also found that the Mary McKinney Company extracted the ore at a cost of about \$21,000 less than the Morning Glory Company could have extracted it, owing to the facilities of the defendant company, and the Mary McKinney Company, it is understood, will make a strong fight for that amount, thus reducing the \$64,000 to approximately \$43,000. Should the minority referee's findings be considered by the Court the award will be further reduced by \$10,000. The referees are J. R. Finlay of Cripple Creek, former superintendent of the Portland; C. W. Howbert, manager of the Vindicator, and E. E. Chase of Denver.

A three-year lease on the Los Angeles, Six Points and adjacent ground near Cripple Creek has been taken by the Exposition M. & L. Co. and D. B. Hill from the Stratton estate. It is proposed to ship medium grade ore, of which there is considerable in sight, and to construct and operate a cyanide mill of 200 tons daily capacity. The Hill lease on this ground was surrendered in consideration of other concessions and the agreement of the lessees to engage in milling. A. Kenyon and C. Grant of Cripple Creek are interested. Ground has been broken for the mill. Machinery capable of crushing 200 tons a day will be installed, but for the present the tank capacity will not exceed 75 tons. Under the terms of the lease the construction of a 50-ton plant and the payment of 17½% royalty, flat, is required.

The Merger G. M. Co., which recently secured the Bonnie Nell property on Raven hill, near Cripple Creek, will sink the shaft down to the 1000-foot point.—Lessee Long and associates of Cripple Creek, who recently secured the Elkhorn and other properties on Tenderfoot hill under bond and lease, have commenced sinking the shaft, which is now down 450 feet.

All leases on blocks of Stratton's Independence mine at Cripple Creek have to be renewed. The renewal affects about thirty-five individual lessees and leasing concerns. Its limitation is six months, as before, and under the same terms as have been required in the past. Of the thirty-five lessees about 95% have shipping ore. The production ranges between 5000 and 6000 tons a month, having an average value in excess of \$25 a ton. Operations are being conducted under the general direction of Manager Becker.

### IDAHO.

#### Boise County.

The new vertical working shaft for the Lincoln mine at Pearl is down 160 feet, and will be sunk to the 500 level before crosscutting or drifting, says Manager G. Z. Edwards. The old shaft caved and was thought beyond recovery for permanent operations.

#### Custer County.

The White Knob Copper Co.'s property at Mackay is being worked by Receiver N. H. Clark with forty men. The main shaft is 700 feet deep, connecting with the 1500-foot Albert tunnel. The property is said to show a 23-foot vein carrying 3% to 9% copper, and \$1.75 to \$3 gold and silver. The mine is connected with the smelter by a 10-mile electric railway, having a maximum gradient of 6% in a rise of 2000 feet. The smelter has three 200-ton furnaces, and was blown in in September, 1902. The company was forced into the hands of receivers last October. It is stated that the trouble with the White Knob enterprise is that its expensive smelting plant and surface equipment were undertaken before the method of treating the ore was sufficiently worked out. The bodies of carbonate and oxide ores have continued down 700 feet in that altered condition to the Albert tunnel level, and experience has shown that the ore lacked sufficient sulphur for a successful matting method of treatment with which it has been attempted to work it, and too much sulphur for making base bullion successfully. The sulphur and copper content has shown increase in two short winzes that have been sunk from the Albert tunnel.

#### Idaho County.

(Special Correspondence).—The Sunday mine, at Big Creek, 35 miles from Warren, owned by S. D. Edwards of Logan, was located three years ago. A shaft has been sunk 50 feet. A tunnel is being run to cut the vein 100 feet below the shaft. This will give 160 feet of backs. The tunnel now is in 125 feet and the ledge will be cut early in May.—A rich body of ore has been opened up on the Edwards and Macy claims, the ledge running parallel with the Sunday vein.

Logan, Feb. 14.

(Special Correspondence).—It is stated that the Boyer mill at Elk City is to start.—J. Mason of the Gold Dove group, near Elk City, reports that their cyanide plant is completed and that they are waiting the arrival of the zinc and cyanide to start operations.

Elk City, Feb. 14.

The Crooked River M. & M. Co. expects to have its cyanide plant at the Hogan mine, near Elk City, completed by May 1. The 20-stamp mill is finished. W. Hogan is manager. Reports that mining and milling at the Hogan are being done for 60 cents a ton are confirmed by R. N. Bell, State Mine Inspector of Idaho, who says that this property carries a zone of altered granite country rock several hundred feet wide, traversing the company's property for several thousand feet, a shattered, schistose, silicified zone of movement that has subsequently been intimately saturated and impregnated with gold-bearing iron solutions, and now represents an average gold value through its great width conservatively estimated at between \$3 and \$4 a ton, of which it is said that 50% has been saved by simple plate amalgamation, and that 90% of the balance may be recovered by cyaniding. The gold disseminated through this mass

of mineral matter is generally very fine, but not all fine, for occasional cavities or seams are found crusted with iron oxide spotted with visible native gold. It parallels the valley of Crooked river, which affords a water power of large capacity. The property has been equipped with a 20-stamp mill, run by water power, and is worked by the glory hole method, which consists of quarrying the material into open raises connecting with a 500-foot tunnel driven in the zone from the back of the mill, where it is drawn off in cars and run out to the mill bin, and goes automatically through to the tailing pile. The mineral is very friable. Deep holes are put in with long churn drills and the heavy blasts thus prepared break it down in large quantities that call for little bulldozing, as the largest boulders can generally be readily broken small enough with a sledge to pass the coarse grizzly bars set at the head of the chutes.

Regarding work in the Thunder Mountain district during 1904, R. N. Bell, in his report as State Inspector of Mines, says: The completion of the Thunder Mountain wagon road, together with the increased bullion production of the Dewey mine, and the successful developments at the Sunnyside, gave the Thunder Mountain district around Roosevelt a boom during 1904, and the camp has made more real progress than during any year of its history. The new road has proven a success. The Dewey mine, the oldest in the district, is equipped with a 10-stamp mill, built in 1901, that had to be made in small sections so that it could be transported on mule-back. It is common experience for a patchwork mill of this kind to give lots of trouble and prove hard to hold up in repair, and this mill is no exception to the rule, but causes lots of trouble and loss of time to its operators to keep it in adjustment. While running, however, it has proven a great gold saver and demonstrated that in good hands the ores of Thunder Mountain yield a little higher percentage of their gross value to plate amalgamation than any other district in the State, close sampling of the battery heads and tails showing an actual recovery of 85% of the total value of the ore as free gold. The plant for an actual running time of seven months produced gold bullion valued at \$78,000. The average values of the ore treated during the year have ranged from \$10 to \$16 per ton. Thirty-five men were employed on the property during the greater part of the year, and in addition to the development of the mine, a great deal of road building and surface improvement was accomplished. The superintendent is Bert Haug. At the Sunnyside mine a crew of from 200 to 300 men were employed during the greater part of the year in the construction of the company's 40-stamp mill and aerial tramway, building roads and other surface improvements. All the machinery for this mill was hauled over the new road, placed in position and ready to run in December. The plant was started up but had to suspend operation immediately, owing to a defect in the tramway, which it is thought can be remedied. The weakness developed consisted of defective grips by which the tramway buckets are attached to the rope. These proved too weak to stand the strain over an unusually long, steep span on the line of the tram. These are to be replaced with stronger attachments. The slopes of the Sunnyside mine are reported to be in shape to supply 150 tons of ore a day. The mine has been quite extensively developed, and the work on the property seems to have demonstrated the occurrence of a blanket shaped deposit of tuffaceous igneous rock, 30 to 40 feet or more in thickness or depth, of wide extent and conformable to the general surface, but capped over at some depth by a barren sheet of harder, igneous formation.

The H. Y. Climax Co., which owns claims near the Dewey mine, have a hoist and sawmill on the property and have ordered a 10-stamp mill. They have let a contract for sinking their shaft to a depth of 400 feet. This company is employing thirty men. The Twentieth Century M. Co. has built a sawmill and are employing ten men in tunnel and other work. The East Dewey G. M. Co. has driven 350 feet of tunneling during 1904, and is now employing four men. There has been a large amount of development work done in the district by different companies and individuals during the year, of which detailed data is hard to obtain; the probably productive area has been widely extended, and intelligent investigation is being carried on at a good many points this winter; the total number of men employed in the different properties tributary to Roosevelt this winter is estimated at 500. At the Warm Lake district, on the Thunder Mountain road at Knox, the Trapper's Flat Co., managed by G. M. Snow of Nampa, are planning to erect a mill next summer. This company has built a sawmill. The Fidelity M. Co. property, located near the above, has similar strong fissure ore bodies containing big milling values and is being actively developed this winter.

#### Shoshone County.

(Special Correspondence).—The 16 to 1 mine at Wallace has closed because of a shortage of water. Fifteen men had been employed. Drifts had been run on the 200 and 400-foot levels, and a raise has been driven from the 200 to the 400-foot level. The mine is now in position to keep the mill supplied with ore.

Wallace, Feb. 13.

The crosscut tunnel of the Nine Mile Co., 3 miles up Nine Mile creek from Wallace, has been driven 150 feet. This extension of the tunnel was undertaken on the advice of the engineers of the United States Geological Survey, who were there last summer and gave it as their opinion, after examining the property and going carefully over its vicinity, that the workings were in a break and would have to be extended 200 to 300 feet to catch the ledge.

It is reported that 150 men will be employed on the Con. Black Cloud & California and the Panhandle mines, 2½ miles from Wallace, on Nine Mile. These properties have passed into the hands of the Heinz Lead & Silver M. Co. of Pittsburgh, Pa. C. H. Maiden, representative of the company, is at Wallace, and under his supervision continuous work has been in progress on the mine. A shaft is being sunk near the mouth of the tunnel to a depth of 200 feet. After taking hold of the Panhandle, the company began negotiations for the California and Black Cloud, situated on the opposite side of the canyon. These are among the oldest and best known locations in

the district. Both have been extensively developed by tunnels and drifts, and from both of them ore has been extracted and shipped. This is particularly true of the California, which, it is said, has paid \$60,000 to \$70,000 in dividends. At the present time, we are informed, there is no less than 500 tons of milling ore in the California bins. The concentrator on the Black Cloud will be started as soon as the water supply is sufficient. J. H. McClarren of Pittsburgh, Pa., president of the company, is expected at Wallace to begin operations on the consolidated properties.

#### Washington County.

The Ladd Metals Co.'s smelter at Landore is shipping matte and is handling sixty tons of ore daily. The matte comes from the smelters as bricks, 24x10x12 inches, and each one weighs 400 pounds.

E. D. Ford, manager of the Salzer-Ford Co., operating at Black Lake, reports that the new mill has been running since October 1 and has been reducing from 1200 to 1500 tons of ore monthly. The ore is crushed through a 12-mesh screen, run into the cyanide vats and left standing four days in a solution of 1%, effecting 92% saving. The cost of milling the ore, including the refining of the bullion and all labor about the mill, is \$1.30 a ton.

#### MISSOURI.

##### Jasper County.

(Special Correspondence).—A good zinc strike has been made by the Sunshine M. Co., 2 miles east of Joplin. They may build a mill. The company is composed of W. Fabrenbach, G. Muenig, W. Drawe and G. Blinzler of Joplin. E. E. Farrell has a good lead prospect on the land south of the Ten O'Clock mine, south of Carterville. The Sparks, Henderson & Stevens mill at Badger is producing close to 100 tons weekly. This mine, on the bank of Spring river, has done much toward exploding the theory that zinc could not be found under limestone. The company is preparing to erect a new 150-ton mill. E. B. Rankin, F. M. Smith and F. M. Cummings of Joplin have sold their mine on the Guengerich land, southeast of Joplin, for \$50,000 to the Lyman G. M. & Co., who propose to work the mine on a larger scale and will begin the construction of a mill. C. C. Wolcott, manager of the New York Zinc Company's land, southwest of Galena, has returned to Galena after a business trip to New York and will start up his mines as soon as possible. For several months the company has had considerable trouble in keeping the ground drained and has spent much money. The latest development of the sheet ore region has been on the C. M. Wilson land. Drilling proved that the blanket vein of zinc and lead extended in that direction and the Winslow M. Co. has been the first to sink the shaft, open up the ground and erect a mill. Eight drill holes showed ore at a uniform depth of 200 feet. The officers of this company are: A. L. Wolfe, Parkville, Mo., president; A. W. Yous, Mound City Mo., vice-president; W. M. Hamsber, Mound City, Mo., secretary and treasurer. The Bullfrog mine, 2 miles south of Joplin, is the largest hand jig mine in the district. Sixty tons of ore have been taken from this mine in a week's operation. J. J. Wickham of Joplin, superintendent of the company, is figuring on erecting a new 100-ton mill.

Joplin, Feb. 13.

#### MONTANA.

The San Francisco, Idaho & Montana Railroad Co., W. P. Mason of Minneapolis, Minn., president, will hold a meeting in New York on February 23 to decide when construction shall begin. They will build a railroad from San Francisco, Cal., to Butte, Mont., a distance of 923 miles, of which 308 miles will be in California, 215 miles in Nevada, 99 miles in Oregon, 284 miles in Idaho and 92 miles in Montana. The route is via Marysville, Oroville and Susanville, Cal.; Old Camp, McGarry and Mason, Nev.; Jordan Valley, Or., and Boise, Ida. There will be a branch line from Mason to Winnemucca, Nev. The road has been surveyed from San Francisco, Cal., to Boise, Ida., 578 miles, and is under survey from the latter point to Butte, Mont., 345 miles. All the bonds have been subscribed and the road will be completed by June, 1907. The country through which the line will pass is undeveloped. Timber, grazing and agricultural lands predominate. The preliminary surveys have all been made. The company has already let several contracts and will receive bids for the rest of the work as fast as the surveys are completed. C. H. Fleming of Minneapolis, Minn., is vice-president; W. E. Foray of Boise, Ida., is treasurer; J. Q. Burbank of Boise is chief engineer, and G. F. Propper of Boise is secretary.

#### Fergus County.

It is announced that the Moccasin Mountain M. Co., owning 500 acres of ground in the Moccasin district, near Lewistown, will soon begin development. Diamond drill explorations have been carried on for several months under the personal direction of W. Moore, with the result that good values have been shown to exist and the ore zone to be an extensive one. The Moccasin is a cyaniding proposition and it is intended to erect a large mill as soon as the development work justifies. The incorporators and trustees are: A. L. Emerson, J. R. McKennie, J. H. House and D. N. Heizer of Colorado and D. R. Beatty of Beaumont, Tex. S. S. Hobson is representative, at Lewistown.

#### Granite County.

Regarding the Boulder district, near Princeton, the Phillipsburg Mail says the sedimentary formation starts at Flint and consists of Cretaceous limestone, about 3000 feet thick, Triassic red sandstone, about 2000 feet, then a bed of quartzite, about 1000 feet in thickness, and on the south side, toward South Boulder, slate or shale for a long distance. At Princeton we find the lower Silurian formations intersected with quartzite. These lower Silurian formations consist mostly of dolomite which is cut by garnet porphyries and shows immense ledges of iron oxides assaying sometimes well in gold and some silver. On Sugar Loaf mountain, ½ mile from Princeton, there is a body of silver-lead and zinc-copper ore which in the past has brought good returns from shipments. The garnet porphyry sometimes carries nuggets of native copper ore assaying as high as 60%. The iron lodes run-

ning parallel with the garnet reefs have never been tried in depth. Sometimes, like in the Gold Hill, they have chimneys which are rich in gold. More than \$30,000 have been taken out at the Gold Hill, which is owned by P. J. Brophy of Butte and the Huffman brothers of Phillipsburg. Magnetic iron occurs in immense bodies. In some of the gulches cinnabar is also found. The Princeton M. Co. of Butte have a silver property 2000 feet from Princeton which is not being operated on account of some friction among certain stockholders in France. Two miles north of here is Princeton gulch, where many thousands of dollars in placer gold have been taken out. Going east from Princeton we still have the lower Silurian limestone for about 18,000 feet until we reach the Mount Powell mines where the formation is occasionally interrupted with granitoid porphyries. About 2 miles south of Mount Powell are the Race Track mines, which lie mostly in the granite belt. Still further south and west are the Red Lion and Cable districts with several bonanza mines, and then the famous old Granite which has produced millions and is still keeping up its record. From Mount Powell mines, at an elevation of 9000 feet, climbing in a northerly direction along the main range, we come to Goat Mountain. Here we find the tilted Cambrian quartzite resting on the Archean granites and cut by granite porphyry. The entire mountain is faulted on veins carrying gold, silver and copper ores assaying high in these metals. Most of the claims here are owned by Phillipsburg parties who work there spasmodically and make occasional ore shipments. Looking East from here we see in about 3 miles distance the highest mountain in Montana—Mount Powell. The country there is very abrupt and the formation is mostly of granite. Here numerous small creeks have their source. There is little Rock creek. Lost creek, Dempsey creek and others. Looking west from Goat mountain, on the contact of granite and slates, we see Finley basin which has good copper-silver-gold claims. Still farther west, and joining the claims just mentioned, are the claims of the Albion Mining Co., carrying the same character of ore as that found in Finley basin. About 1 mile farther west we reach the Royal country which is in the Archean granite, cut by granitoid porphyries. The ores here are principally gold ores, free milling, running well in gold. The principal mine here is the Royal, which has produced upwards of a million in gold.

Adjoining the Royal is the Sunday mine, which is in the same formation with the same character of ore. One mile north from there, still in the granite formation, is the Blue Bird mine, owned by C. Schille. The ores here carry copper, lead, silver and gold. One mile west of here is the Frank Walgren group of claims, fairly well opened up and shipping ore in sight. Four miles north from here is Rose mountain and Pike's Peak, where are located some splendid properties, and which section has a great future. Turning back south-west over a good wagon road, we come to the Nonpareil mine, which has produced quite an amount of lead-silver ore in years past and is likely to be started up again soon. This property is in lime formation. One-half mile from here is located an immense ledge of iron ore (oxides) assaying 65% iron and a little gold and silver for the average width of the vein, which is about 160 feet. The lead can be plainly traced a distance of over 3000 feet. It is owned by Princeton parties. The town of Princeton is 4½ miles east from Flint station at an elevation of 5500 feet. From the railroad station at Flint to the head of Boulder creek is 11 miles. There is a good wagon road toward the Mount Powell and Royal mines. Most veins in the lime formation run northwest by southeast, and east and west in the granite. The country around Princeton is much folded and faulted. Some faults can be traced for a distance of over 6 miles and quite a few ledges occupy fault fissures. South of Princeton, about 3 miles, is the Gold Reef group of mines. The lodes here are mostly in slates and porphyries. They are of good size and carry good values, principally gold. Some of the ore also carries telluride. There is a considerable amount of development work being done there. A modern stamp mill is being built to treat the ores.

#### Silver Bow County.

Much alarm is felt by Butte people because the streets are settling. It is stated that mining operations are going on within ten feet of the surface, and that in consequence the streets are in dangerous condition. The greater part of Butte is built over mines, and at times it is possible to hear the miners at work in tunnels beneath the surface.

#### NEVADA.

##### Esmeralda County.

The Nevada Coal Co., owning the coal mines at Coal-dale, 3 miles from the Tonopah Railroad, and in which F. A. Keith, T. L. Oddie, H. A. and A. Tripp are interested, will prospect the deposits with a diamond drill with a capacity of 1500 feet. The croppings are lignite and it is hoped to find a semi-bituminous coal with depth. A gasoline hoist is to be put on the Daisy mine, at Diamondfield, by the Diamondfield G. M. Co. A. S. Watson is manager. The 5-stamp mill at Silver Peak has started.

V. T. Hoggatt of Denver, Colo., has bought from L. Harris and partners seventeen claims near Amargosa, and have organized the Lige Harris-Bullfrog M. Co. to develop them. The Goldfield-Sovereign M. Co. has purchased from F. E. Horton and T. Henry, R. T. Brackney and L. Griggs claims ½ mile north of the Kendall mine, near Goldfield. F. E. Horton of Goldfield is resident manager. The Goldfield-Combination M. Co. has been formed at Goldfield by W. T. Liggett, D. S. Karns, J. P. Sweeney and H. C. Davis to work the Combination mine, which they have bought.

##### Lincoln County.

The Deer Lodge M. Co., operating at Deer Lodge, 24 miles from Uvada, Utah, will put in an air compressor to rush work on the 900-foot tunnel being driven to cut the ledge; the tunnel has been run 165 feet. E. D. Trenam is manager.

G. Surr is building a 25-ton cyanide plant to treat the tailings from the Cyrus Noble mine near Searchlight. The shaft of the Quartette mine at Searchlight is

nearly 800 feet deep. The west drift of the 700-foot level is in 75 feet in good ore.

The Moapa G. & C. M. Co. has been formed at Provo City to work claims in the Cane Springs mountains. S. K. Roberts is president, J. K. Bishop vice-president, H. G. Blumenthal secretary and J. W. Lamb treasurer—all of Provo.

#### Nye County.

(Special Correspondence).—W. A. Stanton, who has returned from the Kawich mining district, 70 miles east of Goldfield, reports that the same geological conditions are present in Kawich, and the surface showings are the same as those in the Goldfield district. Two hundred men are now in the district, and most of these make Goldfield their headquarters. Fifty buildings have been constructed.

Goldfield, Feb. 13.

#### White Pine County.

J. Ferren, superintendent of the Glasgow & Western Exploration Co., developing the Star mines at Cherry Creek, states that the company is sinking the shaft deeper and will not stop until it is at least 1000 feet down. More powerful machinery will be put in.

### NEW MEXICO.

#### Grant County.

At Hanover, J. W. Bihlo has purchased the Humholdt mine from J. Schlosser and R. La Franz; the Copper Kettle, Copper Queen, Mabel and Feltus mines from C. Abrahamson, H. Feltus, W. Welty and C. McCarthy, and the eight claims of the Pinto Copper Co. in the Central district. These last show four veins carrying carbonate and sulphide ores said to average 20 feet in width, and to carry good values in copper, silver and gold.

#### Otero County.

The Standard Lithographic Stone Co., 6 miles north of La Luz, on which work has been in progress for some time, is putting up extensive works for the preparation of lithographic stone for the market. The stone found on the company's property has been carefully tested, and has been found equal to the best Bavarian stone. The company is making arrangements to put it on the market on a large scale. The plant includes a gang of twenty saws, a polishing machine, compressed air drills and other machinery. Power will be furnished by a 50 H. P. engine. The machinery has been received and is now being erected, but it will probably be two months before it is in complete working order. In addition to the machinery for preparing the stone, the company intends also to put up a plant to make cement and other by-products from the waste and refuse incident to quarrying and preparing the stone. This will be the first place where lithographic stone is worked in this country on a commercial scale.

#### Rio Arriba County.

Through an injunction the Dillon Dev. Co., which has been operating a property in the Bromide mining district, has closed down and the Bromide Mining Co., which claims to be the original owner of the property, has taken charge. The Dillon Dev. Co. has developed the property extensively, installed machinery and erected buildings on it. It is said that the old company, composed of St. Louis men, will resume operations at once.—The New Mexico G. & C. M. Co., with offices at Tres Piedras, are working the Strawberry mine in the Bromide district. This shows fissure veins in schists and contact veins between schist and granite. R. Cole is superintendent.

#### Socorro County.

It is said that the Dividend M. & M. Co. of Estey City, which owns a leaching plant and 100-ton smelter, is contemplating removing the same from Estey City to Alamogordo. At present the company is unable to run the plant owing to lack of water. If the leaching plant and smelter were removed to Alamogordo they would be midway between Jarilla and Estey City, and the ore could be easily hauled to the smelter.

It is reported that the Tri-Bullion M. Co. will put in a concentrating plant at the Kelly mine at Kelly. H. Paschal is general manager at 307 Dearborn Building, Chicago, Ill.

### OREGON.

#### Baker County.

Operations at the Taber Fraction, near Bourne, continue from the lower levels of the Columbia mine, giving a depth of 1100 to 1200 feet.—The Sumpter smelter has put on double shifts, doubling the capacity of the plant. All of the bins at the smelter are filled, and the management has been forced to adopt many expedients to accommodate the daily tonnage. After two shifts start at the furnace, the surplus will be worked off, and until receipts increase further, the smelter will be able to handle ore as it is delivered. New bins have been arranged and these will be kept full while deliveries are constant.

More than 9000 feet of flume has been finished in the ditch system of the Oregon M. & I. Co., and Manager F. W. Talmage of Sparta will build further in the spring. The enlarged system of this company will deliver much more water from Eagle creek to the Sparta district, and enable placer owners to work larger acreages. The canal is the largest yet completed in this part of Baker county. It took for its nucleus the old Sparta placer ditch, which has been enlarged and extended. The result of the company's work insures heavier placer operations in Sparta next spring than the district has seen for many years.

#### Grant County.

Z. Houser has started his 5-stamp mill near the Standard mine, near Pralrio City.

#### Josephine County.

Manager A. B. Cousin and Superintendent E. F. Terry of the Galice Con. placer mines, near Galice, state that the bedrock flume being built by the company to work the bed of Galice creek from the Rogue river bar is progressing rapidly, and that four giants are in steady commission. They intend to install the Campbell tubular elevator on Gamhler's bar, at the mouth of Rogue river, as soon as the spring freshet of the Rogue is past. As the bedrock of this bar is but a feet above the river, it has never been deemed amenable to hydraulic meth-

ods. By means of the elevator this will be overcome and the Galice management will wash the entire bar, which embraces about sixty acres of promising placer ground. The highline ditch will be extended so as to reach the ground with a pressure of 300 feet to handle 1500 to 2000 cubic yards of gravel a day for seven or eight months of the year.

The Mt. Pitt M. & M. Co. are treating high-grade ore from the Climax mine in the upper Jump-off-Joe district in two tuh arrastras run by water power. A. C. Hooper has charge.—The Harmon-Green placer at Galice is being worked by T. K. Anderson.—F. V. Metts and O. L. Leigh have driven 900 feet of tunnel to drain the Silver Creek basin preparatory to mining the rich detrital deposit.

#### Malheur County.

At the Uncle Sam group, Mormon basin, near Malheur, sinking is being pressed since the new hoisting plant was completed. The management announces the purpose of going to the 300 level immediately, cutting stations and drifting each 100 feet. Lumber is being manufactured for a milling plant, which is a part of the year's programme.—Twelve to fifteen men are working at the Hattie B. property, Mormon basin. The property is owned by the Commercial M. & M. Co. of Portland.

### SOUTH DAKOTA.

#### Lawrence County.

The Spearfish M. Co., near Spearfish, has put a hoisting plant at the main shaft to explore the lower ore contact recently opened up.

#### Custer County.

The second shift of men has been put on at the Saginaw mine, near Custer. At the 250-foot level in the shaft a crosscut is being run toward the three parallel veins of ore. The shaft is also being sunk deeper. This company intends to build a cyanide plant in the spring.

### WASHINGTON.

According to the United States Geological Survey reports, the mineral output of Washington for 1903 was:

	Value.
Coal (3,163,273 tons).....	\$8,380,954
Clay products.....	928,265
Gold.....	507,885
Silver (294,500 ounces).....	159,080
Coke.....	214,776
Gas.....	429,963
Quarry products.....	594,343
Copper (80,756 pounds).....	10,820
Lead (538 tons).....	45,500
Coal tar.....	23,210
Mineral waters.....	10,550
White arsenic.....	36,691
Total.....	\$9,342,097

#### Kittitas County.

The Washington Quicksilver Co. has sold its property near Roslyn to D. C. Corbin of Spokane for \$400,000. An electric road will be built from Roslyn to the properties, a distance of 30 miles.

#### Okanogan County.

(Special Correspondence).—The Ruby M. Co., on Chopaca mountain, near Nighthawk, which has been doing prospecting and development work on its claims for eighteen months, has uncovered ore that assays \$50 a ton. A shaft was originally sunk 200 feet on Chopaca mountain and two crosscut tunnels were run. Exploration of the main ore body shows that the vein is from 3 to 20 feet in thickness. It has been uncovered 200 feet deep and 1400 feet in length. The main body of the ore is a soft sulphide, easily worked and lying in an outside casing of talc, surrounded by granite. The values are silver, gold, copper and traces of zinc and lead. The shipping ore averages \$50 a ton. Five hundred tons have already been taken out, and six 200-foot shoots in the mine have been filled. J. M. Haggerty, the president of the company, has been East with a quantity of samples of the ore, in order to have analysis and a reduction process devised. Baker & Burwell, Ohio, have devised an electric chlorination process, and will install a 20-ton plant at a guaranteed maximum cost of \$2.50 per ton. The electrical current is to be supplied by the Similkameen Falls Power & Development Co.

Nighthawk, Feb. 13.

#### Stevens County.

(Special Correspondence).—W. H. Plummer, secretary and manager of the New National C. Co., has taken up the \$75,000 bond on the Butte mines, near Springdale, and has started work under the superintendency of T. Hye. The Butte group has been developed by 600 feet. Springdale, Feb. 13.

(Special Correspondence).—The Frisco Standard M. Co. on Fish creek, 16 miles northeast of Northport, will install a concentrator at the mine.—L. P. Larson, manager of the Last Chance, on Deep creek, east of Northport, is working the Washington group on Red Top mountain.—The Galena Queen, on Stoddard mountain in Deep Creek valley, in sinking a shaft 100 feet by contract. The property improves in galena.

Northport, Feb. 13.

### FOREIGN.

#### BRITISH COLUMBIA.

##### Boundary District.

According to Manager J. P. Graves in the official statement of the metal produced by the Granby Con. Co. in 1904, nearly the entire output of the smelter came from the ores of the Granby mines. No outside matte was converted and the volume of custom ore which was handled was small in 1904. The Granby Co.'s metal output was: Copper, 13,431,226 pounds, at 12.8c, \$1,719,196; gold, 47,968 ounces at \$20, \$959,360; silver, 180,844 ounces at 57c, \$103,081; total, \$2,781,637. The Granby Co. has bought the Monarch group for \$160,000.

The tonnage of ore shipped by the several mines of the Boundary for January was: Granby mine, tons, 40,450; Mother Lode, 13,696; Brooklyn-Stemwinder, 6849; Rawhide, 2251; Sunset, 726; Mountain Rose, 682; Emma, 1849; Oro Denoro, 298; Senator, 918; Providence, 50; Elkhorn, 50; Skylark, 39; Last Chance, 43; E. P. U. mine, 65; Bay, 42; miscellaneous, 75. Total tons, 68,083.

#### Nelson District.

The Ymir mine at Ymir has seventy-five men employed at the mine and mill, and there is no immediate prospect of any further reductions. The cutting down has been caused by the cessation of development work on the deep levels. Meanwhile the stamp mill is crushing ore from the upper levels, where there is now enough in sight to supply it for some time to come. The Ymir mine, like many other mines in the province, has this year been severely handicapped by a scarcity of water, which has necessitated running the stamps by steam power. As wood is now somewhat scarce in the immediate vicinity of the mine, this has made milling a much more expensive process than in the past, and the profits obtained from milling under these circumstances do not admit of much expenditure by way of development. As soon as the snows begin to melt, however, there will be an abundance of water for all purposes. The 80-stamp mill has 850-pound stamps with a 6½-inch drop, ninety-eight to the minute. Narrow mortars with No. 9 and 11 diagonal slot screens have been used, the height of discharge being 3½ to 5 inches. The crushing capacity has been from 2½ to 3 tons per stamp per twenty-four hours. The ore is white massive quartz containing 8% to 12% of pyrite, sphalerite and galena. E. C. Holden has reported the saving on the plates to be 61.9% of gold values and 9.4% of silver. The saving in the concentrates was gold 16%, silver 35.4%, lead 42%, giving a total of 77% extraction. The vanner tailings are cyanided. G. H. Burnhart is manager.

#### Southeast Kootenay District.

(Special Correspondence).—A meeting of the Golden River M. Co. will be held on the 20th of March at Seattle, Wash., to increase the capital stock. Machinery will be installed during the coming season. R. J. James of Seattle is one of the trustees. The company is working on Bull creek, intending to divert the stream and mine the diggings in the bed of the river.

Fort Steele, Feb. 12.

#### Victoria District.

M. K. Rodgers, acting for the Daly Reduction Co., which owns the Nickel Plate, in the Similkameen, has bonded twenty-five claims on the Bonaparte river, near Ashcroft, for \$500,000.

#### Yale District.

(Special Correspondence).—S. Henderson of Ashcroft has sold the big copper mine on the Savona, 12 miles from Ashcroft, to the Marcus Daly people, for \$150,000. Ashcroft, Feb. 13.

### CANADA.

#### Yukon Territory.

The Department of the Interior of British Columbia publishes the following regulations governing mining in the Yukon Territory: Dredging: Six leases of 5 miles each may be granted to a free miner for a term of twenty years, renewable. The lessee's right is confined to the submerged beds or bars in the river below low water mark, that boundary to be fixed by its position on the first day of August in the year of the date of the lease. The lessee shall have one dredger in operation two years from the date of the lease, and one dredger for each 5 miles, within six years from such date. Rental \$100 per mile for first year and \$10 per mile for each subsequent year. Royalty same as placer mining. Placer: Creek, gulch, river and hill claims shall not exceed 250 feet in length, measured on the base line or general direction of the creek or gulch, the width being 1000 to 2000 feet. All other placer claims shall be 200 feet square. Claims are marked by two legal posts, one at each end, bearing notices. Entry must be obtained within ten days, if the claim is within 10 miles of mining recorder's office. One additional day allowed for each 10 miles or fraction. The person or company staking a claim must hold a free miner's certificate. The discoverer of a new mine is entitled to a claim 1000 feet in length, and if the party consists of two, 1500 feet altogether, on the output of which no royalty shall be charged, the rest of the party ordinary claims only. Entry fee \$10. Royalty at the rate of 2½% on the value of the gold shipped from the Yukon Territory, to be paid to the comptroller. No free miner shall receive a grant of more than one mining claim on each separate river, creek or gulch, but the same miner may hold any number of claims by purchase, and free miners may work their claims in partnership by filing notice and paying fee of \$2. A claim may be abandoned, and another obtained on the same creek, gulch or river, by giving notice and paying a fee. Work must be done on a claim each year to the value of at least \$200. A certificate that work has been done must be obtained each year; if not, the claim shall be deemed to be abandoned and open to occupation and entry by a free miner. The boundaries of a claim may be defined absolutely by having a survey made and publishing notices in the Yukon Official Gazette. Hydraulic: Locations suitable for hydraulic mining, having a frontage of from 1 to 5 miles, and a width of 1 mile or more, may be leased for twenty years, provided the ground has been prospected by the applicant or his agent, is found to be unsuitable for placer mining, and does not include within its boundaries any mining claims already granted. A rental of \$150 for each mile of frontage and a royalty at the rate of 2½% on the value of the gold shipped from the Territory are charged. Operations must be commenced within one year from the date of the lease, and not less than \$5000 must be expended annually. The lease excludes all base metals, quartz and coal, and provides for the withdrawal of unoperated land for agricultural or building purposes. Petroleum: All unappropriated Dominion lands in Manitoba, the Northwest Territories and within the Yukon Territory are open to prospecting for petroleum, and the minister may reserve for an individual or a company having machinery on the land to be prospected an area of 640 acres. Should the prospector discover oil in paying quantities, and satisfactorily establish such discovery, an area not exceeding 640 acres, including the oil well and such other land as may be determined, will be sold to the discoverer at the rate of \$1 an acre, subject to royalty at such rate as may be specified by order in council.

## MEXICO.

## Chihuahua.

The approximate production, in tons, of Parral for January was: Shipped to smelters, 13,006; locally treated, 15,437; held for future delivery, 24,214; total, 52,675.

The Calera M. Co. has a concession for the construction of a branch railroad line to handle ore and supplies between San Isidro and the Calera hill in the Guerrero district. The work of construction must begin during the month of February, and the Calera Company, or a subsidiary company organized by it, will have the privilege of operating the railroad for a period of forty years. In consideration of the amount of money to be expended on the work and of directly beneficial character for the State, the Legislature of Chihuahua has exempted the capital invested from all sorts of State taxes or contributions for fifteen years.

The Compania Minera Palmilla has put in three electric pumps at the Palmilla mine at Parral to drain the mine and irrigate the valley below. Additional men have been put at work. P. Alvarado is owner and manager.

New concentrating tables have been placed at the mill of the Pittsburgh-San Jose Reduction & Railroad Co. at San Jose del Sitio, via Gabilan. The 17-mile railroad from the mill to Vallecitos is almost completed. M. B. Place is manager.

The Chihuahua Enterprise reports that G. Wichtrich of Chihuahua has bonded the Caracalia mine, 7 miles southeast of the Placer de Santo Domingo, to W. V. Petit of Parral.—The Coahuila M. & S. Co. has taken options on the Sierra Rica silver mine in the eastern part of Chihuahua, and the Canares copper mine, both belonging to the estate of E. Miller. The latter property is near the Placer de Santo Domingo. This same concern recently took two copper properties near Cuchillo Parado in the same section. Work is already started on these, and on the Sierra Rica and Canares work is to be commenced at once. A. Bange, mining engineer of the company, is in eastern Chihuahua examining some property with a view to its purchase. The Coahuila Co. has its Mexican headquarters at Viesca, Coahuila. It is operating successfully and extensively mines in that State, Zacatecas and Durango, and is one of the heaviest producers of ores in northern Mexico. W. A. Parker of St. Louis is secretary and manager.—The approximate production of Parral for January was as follows: Shipped to smelters, 13,006 tons; locally tested, 15,437 tons; held for future delivery, 24,214 tons; total, 52,675 tons.

The January output of bullion from the Ocampo district was as follows: Conchena, 12 bars, \$24,000; Sahuayacan M. Co., 2 bars, \$13,000; Cia. B. Sahuayacan, 1 bar, \$4,000; Belen, 8 bars, \$32,000; Siqueiros, 4 bars, \$6,000; Waterson, 6 bars, \$12,000; Pinos Altos, 1 bar, \$500.—J. D. Knotts, who is mining near Guadalupe y Calvo in the southwestern part of Chihuahua, says that Senator Clark of Montana has an option on the Rosario mine in Guadalupe y Calvo at \$150,000 in gold, and has J. A. Peacock in charge pumping out the mine for examination. J. D. Knotts is president and general manager of the Isis G. M. Co. in the Santa Ramona district, 25 miles east of Guadalupe y Calvo. He has a 5-stamp mill and all machinery, including a cyanide plant, which are to be placed on the property. A depth of 150 feet has been reached. The ores average above \$20 in gold value in gold and silver. The process is to be plate amalgamation, with cyanide for the tailings.

W. C. Greene of Cananea has purchased the Santa Juliana gold-silver mine in the Ocampo or Jesus Maria district, and the water power of the falls of Basiachic, for \$438,000 gold. Greene bought the Belvanera M. Co., in which J. C. Beatty of New York is interested.

## Coahuila.

The Cia. Metalurgica de Torreon, owner of the Torreon smelter, reports the yearly profits for 1904 as \$629,279.50. The total tonnage smelted was 201,612 tons of ore and fluxes. Two more furnaces were added to the plant, and now the Torreon smelter has in constant operation eight furnaces. The Torreon Co. owns and controls 130,000 tons of lead ore, blocked out in the Cabrillas mine, near Saltillo, on the National Railroad; San Diego mine, in Santa Barbara, Chihuahua; Las Adargas, near Jimenez, and also in the Voladora mine, Aztec and Carbonato properties adjoining Voladora. Authority has been given to install three copper furnaces in Torreon and a hessomerizing copper plant. The company will proceed at once to erect the building for the new addition. E. Madero is president, C. Gonzales vice-president, L. P. de la Pena secretary and L. P. T. Saldana treasurer.

## Durango.

On February 1 the Guggenheims closed down the mines of its Velardena M. Co. at Velardena to build the new 1000-ton smelter, which will be completed this year. About 2000 men were let out and they are scattering out to other camps in search of employment.

## Guanajuato.

T. H. Leggett of South Africa has been in Guanajuato examining mining properties. He speaks well of the Guanajuato Con. M. Co., operating the Serena mine in the south end of the Veta Madre of the Guanajuato camp. Ore running 600 grams silver and 3 to 4 grams gold is being encountered in a 3-foot pay streak of sulphide of silver, in the workings 200 feet below the old workings and 700 feet below the old tunnel level. In the old workings above the tunnel level a parallel vein of good ore has been encountered in the foot wall. The company's plant consists of a 60-stamp mill, concentrators and pans, but the last are being taken out and the cyanide process is being substituted. The cyanide plant will have a capacity of 150 tons daily. F. G. Corning is consulting engineer. M. E. McDonald is manager.—The El Cubo M. & M. Co. is working the Villapando, Santa Cruz, La Loca and Capolin mines, 5 miles from the city of Guanajuato. It has a concentrating plant of fifty tons daily capacity. The tailings are treated by the cyanide process.

## Guerrero.

E. E. Noon, superintendent of G. Mitchell's La Dicha mines, says the survey of the railroad from San Marquez Bay, 12 miles south of Acapulco, has been completed to

the mines, a distance of 138 kilometers. He says work is to be pushed thereon as rapidly as possible, and that as soon as it is completed a 1000-ton plant will be built at tide water. At Acapulco the company has machinery and materials on hand for a 200-ton smelter, which is being transported to the mines, where it will be put up. This is to be completed in four months. The development work on the mines is progressing.

## Jalisco.

G. E. Purnell, president of the Guadalajara Banking Co., is preparing to reopen and work the Boca Ancha mine, in Parnaso camp. The mine is equipped with boiler, pump and hoist, and plans and specifications are being made for the erection of a reduction plant.—The Compania Minera Asturiana, composed of Guadalajara and Etzatlan capitalists, is unwatering and reopening the Camichi mine in Etzatlan.

## Sonora.

The Morelos D. Co. will put a crushing mill on the Santa Rosa at Morelos in the Moctezuma district, 75 miles south of Douglas, Ariz. B. Brown has charge at the mine.

The Quintera M. Co., operating at Quintera, 6 leagues from Alamos, has a copper furnace en route to its properties. The ores have changed so as to require this change to supplement the present concentration and lead smelting process.—A. Yaeger, representing W. S. Craz of Nogales, and associates of California, is closing a deal for the purchase of the Minas Nuevas mines, near Quintera. The mines belong to A. Goycoolea.

The Roy mine in the Pilares de Teras section of the Moctezuma district is to have a lixiviation plant, but its capacity is not decided upon. The present plant is of 10 tons capacity. Work is going on on the property with good results. A good amount of high-grade ore has been shipped to El Paso during the past year. H. Smith is superintendent.

## SOUTH AFRICA.

## Rhodesia.

The total gold output of Rhodesia for December amounted to 28,100 ounces Mashonaland: 19,847 tons, 6623 ounces; tailings, 8080 tons, 1408 ounces Matabeleland: 50,327 tons, 17,031 ounces; tailings, 19,464 tons, 3038 ounces. The mineral returns for 1904 were:

	Gold, Ounces.	Silver, Ounces.	Lead, Tons.	Coal, Tons.
January.....	19,359	3,521	34.66	5,299
February.....	18,973	3,451	29.10	2,511
March.....	17,756	5,453	33.60	5,527
April.....	17,802	4,275	32.18	5,420
May.....	19,424	4,062	35.12	3,788
June.....	20,402	5,225	33.93	5,416
July.....	24,339	5,700	37.80	5,864
August.....	24,669	6,276	40.32	4,483
September.....	26,029	6,325	35.35	5,298
October.....	24,919	7,567	41.76	4,978
November.....	26,183	8,923	57.40	5,457
December.....	28,100	7,351	43.00	5,646
Totals.....	267,737	67,759	443.70	59,778

## Transvaal.

According to the Mining Journal, November, 1904, gold returns were: Number of mines making returns: Rand, 59 (5185 stamps); Heidelberg, 1 (50 stamps); Barberton, 5 (140 stamps); Klerksdorp 1 (— stamps); Lydenburg, 2 (75 stamps); total 68 (5465 stamps):

	Ounces Fine.	Value.
Mill.....	203,570	£ 864,717
Concentrates.....	17,488	74,284
Sands.....	87,228	370,517
Slimes.....	15,524	65,941
Banks, etc.....	201	852
Rand totals.....	324,011	£1,376,311
Outside totals.....	12,156	51,636
Transvaal total.....	336,167	£1,427,947

## SOUTH AMERICA.

## Colombia.

The United States consular agent at Quibido reports that the Choco gold output is mostly from small placers worked by negroes, who are very proficient in diving to the river bottom when the occasional droughts enable them to reach the pay streak and fill their bateas with gold and platinum-bearing gravel. Modern gold dredgers are being arranged for. In quartz mining, the Davaiba mine has been fitted up with five small wooden steel-shod stamps. This mine is on the cordillera between the headwaters of the Andagueda and Atrate rivers.

## Obituary.

J. H. NEUBAUMER of Springfield, Tuolumne county, Cal., was killed by a cave at his mine near Tuttleton February 5th.

M. D. GREVE of Cripple Creek, Colo., was killed February 8th by falling 25 feet from a bucket in the Rebecca shaft, death probably being due to heart failure.

J. B. BROOKS, a pioneer in the mining industry of Colorado, died at Aspen, Colo., February 7th, aged 77 years. He is said to have smelted the first ore in the first Pitkin county smelter, erected by himself.

## Books Received.

"The Twenty-fifth Annual Report of the Director of the U. S. Geological Survey" is a 400-page volume detailing the work of the Survey for the year ending Jan. 30, 1904. In the description of the geological work done it gives a brief account of the results obtained as shown in bulletins and papers, containing some interesting information regarding mining in Alaska. The magnitude of the topographic work in this country is presented in detail—\$1,087,819 being spent for various purposes during the year.

## Personal.

J. BRESNAHAN has charge of the Kootenay Belle mine at Salmo, B. C.

S. L. BROWN of Los Angeles, Cal., is at Indian Gulch, Mariposa county, Cal.

G. G. GILLET is manager of the Quebridillas mine at Parral, Chihuahua, Mexico.

F. B. WHITMORE has been appointed superintendent of the Columbus M. Co.'s mill at Alta, Utah.

J. VERT of Pendleton has been appointed receiver of the Golconda Con. M. Co., near Bourne, Or.

J. W. BENNIE, general manager of the Shannon C. Co., Clifton, Ariz., has been visiting in Utah.

W. W. KIRBY has returned to Colorado Springs, Colo., from a three months' stay at Goldfield, Nev.

J. D. WHITNEY is superintendent and owner of the New York mine, near Greenville, Plumas county, Cal.

G. RILEY of Idaho Springs, Colo., is superintendent of the Brazil mine, near Lamartine, Clear Creek county, Colo.

D. H. BRIEN is manager of the Tamarack & Chesapeake mine in the Nine Mile district, near Wallace, Idaho.

P. H. BATES has retired as manager of the Pacific Mines of Portland, Or., being succeeded by W. B. D. Dodson.

P. MASON is superintendent of the Golden Scepter gravel mine near Bunker Hill, near Downieville, Sierra county, Cal.

THOS. MANSFIELD of Eureka, Utah, has succeeded C. L. Amsden as superintendent of the Blackbird mine at Frisco, Utah.

R. B. HULCHINSON is manager of the Conchena mines, 80 miles west of Minaca, in the district of Rayon, Chihuahua, Mexico.

M. M. JOHNSON of Salt Lake City, Utah, has been examining the mines of the Montreal & Boston C. Co. at Greenwood, B. C.

W. N. WILBUR, of Hawkinsville, Siskiyou county, Cal., has gone to San Jose Costa Rica, Central America, to engage in mining.

J. B. FLEMING, superintendent of the White Pine C. Co. at Ely, Nev., is studying ore reduction methods at Butte and Anaconda, Mont.

E. C. KNOX has been elected secretary and treasurer of the Montana-Tonopah M. Co. at Tonopah, Nev., succeeding R. P. Dunlap, resigned.

L. S. OVITT, secretary of the Turnagain Arm Co., has been visiting the California, Cracker-Oregon and Cracker Jack groups, near Sumpter, Or.

CARL R. DAVIS, late superintendent of the Center Star and War Eagle mines, Rossland, B. C., is in San Francisco, Cal., en route to South Africa.

T. H. LEGGETT of South Africa and W. M. Brodie of Chihuahua have been visiting the properties of the El Cubo M. & M. Co. in Guanajuato, Mexico.

WM. O'BRIEN has been appointed manager of the Moyer mine at Leadville, Colo., to take the place of J. F. Walsh, who has resigned as superintendent.

J. P. COLPH has been made mine boss at the Gold Reef mine at Giltedge, Fergus county, Montana, taking the place of R. Trumbull, who has gone to California.

J. H. MCBRIDE has been at the La Sal copper mine, 20 miles from Norwood, San Miguel county, Colo., owned by the Copper Glance M. Co., of which he is manager.

M. M. HOWE, superintendent of the Senator tunnel, near Breckenridge, Colo., has been called to Boston by the company to consult about further development work.

R. H. STEWART has been appointed superintendent of the Center Star and the War Eagle mines at Rossland, B. C., and M. E. Purcell has been made assistant superintendent.

A. H. BROWN has resigned as mining engineer of the Consolidated Mercur at Bingham, Utah, to accept a position with the Kitty Burton M. Co., near Salmon City, Idaho.

L. HUMPHREYS has returned from a two years' trip into Central America in behalf of the Venture Co. and the Guggenheim Exploration Co., and examining property at Kennedy, Nev.

C. A. WIEN, who has been in charge of the San Juan mine of the Southern M. & D. Co., in Santa Eulalia, Chihuahua, Mexico, has gone to Dragoon Summit, Arizona, to take charge of another property of the same company.

G. E. SCARFE of Nevada City, Cal., has been named as manager of the South Yuba Water Co.'s Nevada division in place of W. F. Englebright, resigned. W. E. Meserve has been appointed foreman under Mr. Scarfe of the lakes, flumes and ditches in Nevada county. R. E. Linder of You Bet has been made foreman for the Placer county division, with headquarters at Towle. W. R. Artbur of Auburn has been appointed manager for Placer county.

## Trade Treatises.

General Catalogue No. 15 of the C. O. Bartlett & Snow Co. of Cleveland, Ohio, is an illustrated description of elevating, conveying, mining and milling machinery sold by this company. It contains suggestions valuable to those interested in the economical handling of material.

Single Copies, Ten Cents.

## Nevada and Her Resources.

Carson City is the county seat of Ormsby county and the State capital of Nevada. In the early history of Nevada the site of Carson City was not unlike the surrounding country—a sagebrush-covered valley. With the coming of the miners, Carson City came into existence, and by means of irrigation the Carson valley has become wonderfully fertile. Although the agricultural and stock-raising industries of Nevada are, in the aggregate, large, and represent a financial investment of millions, it is the mineral resources of the State which have brought it fame. For forty-five years, since the discovery of the Comstock Lode at Virginia City, Nevada has been the field of active mining development. Within the State are many noted mining districts and towns, some of them now only a memory, others comparatively idle, but for which better days are undoubtedly in store, and still others active and growing daily, with a promise of rivalling the most noted of the past. Among the old and famous districts which produced millions, and whose fame attracted the restless thousands, are Virginia City, Eureka, Tuscarora, Pioche, Austin and White Pine. Besides these, there were a score of lesser camps, such as Tybo, Silver Peak, Pahranaagat, Reveille, Hiko, El Dorado Canyon and many others. In more recent times the new districts of Tonopah and Goldfield are attracting the same amount and kind of attention as that which the others mentioned received in earlier days; but, without doubt, the social conditions now are better than they were forty years ago. The courts now settle the disputes which in former times were sometimes settled "out of court" in a most prompt and positive manner. Lawlessness is not a characteristic feature of Nevada's newer life. The State organization is as perfect as that of any other State, and the character of State institutions is as good as those found in older and more staid com-

munities where the populace is not periodically prone to get out in the middle of the night and start on a journey of several hundred miles with pack animals to join a new rush to the latest gold discovery. However unstable this sort of thing may appear to the outsider, it shows clearly the kind of material of which the average Nevada citizen is made. He is energetic, equal to almost any emergency and he has built and abandoned cities while others in different States slept on peacefully and contentedly.

The accompanying engraving is that of Carson City, taken from "Greater Nevada," and shows the beauty of the situation. The streets are lined with trees, handsome lawns surround the residences and the public buildings are of beautiful architectural design and substantially built. Many of the successful mining men of the State make Carson City their home, and the city is growing in prosperity and numbers annually.

The mineral resources of the State are still largely

undeveloped, owing to lack of economical transportation facilities. There are mines in almost every mountain range and valuable saline and other deposits in nearly every valley of the State. These, in time, will add to Nevada's wealth and greatness, for it is not gold and silver alone that are found in Nevada. There are great lead and zinc deposits, and copper prospects are abundant in numerous places. One of the greatest copper mines of the West is now being developed near Ely, in White Pine county. There are large copper veins in Esmeralda county and unknown gold and silver mines in every county in the State. Many of these are not available to-day by reason of existing conditions, but these conditions must change. With government assistance, irrigation will render larger tracts of the fertile valleys productive. Electricity will do much for the development of the mines, and railways must solve the transportation problem, which has been the chief drawback to the development of Nevada's resources.

Carson City, the Capital of Nevada.

THE principal reasons for the success of the American engineer lies in his versatility, his initiative and ability to adapt himself to a novel situation. He endeavors to be accurate and painstaking, but is flexible and will quickly drop a cherished idea if he discovers the idea is at fault and that something else answers the purpose better. He shuns "rule of thumb" and usually has a good reason for adopting a plan or method, and does not follow it because his father, or some noted engineer of a decade ago, employed it. Any opposition to scientific research and the application of scientific methods is rapidly disappearing, for it is found in most branches of industry that science is a synonym of profit, and traditional methods are no longer to be trusted to give the best results.

THE recent decision of the Federal Court at St. Louis, Mo., that the Stratton estate cannot be held for damages by the Venture Corporation of London, under the plea that the mine had been salted, again clearly places the responsibility on the buyers, in the event of mining sales. The Stratton's Independence mine was carefully examined and found to be a very valuable property. If the promoters overstated the value of the property the original owners cannot be held responsible. This case has almost a parallel in the Seven Stars case of Arizona, in which promoters claimed much more for the mine than could be demonstrated at the time by examination. In this case, also, the Federal Court held that the original owners were not responsible for the misrepresentations of the promoters.

STEEL is being employed more and more in mining work and construction. It is only a few years since the first steel head frame was erected over a Western mine. Some mine superintendents looked upon the steel frame as an element of great danger—likely at any time to be demolished by a flash of lightning, but, although steel head frames are now becoming common, no such catastrophe as at first feared has been reported. Steel is entering still

more into underground work where it can be employed advantageously. Concrete also finds a constantly increasing application about mines in surface construction, and there is a drift of sentiment toward more substantial and permanent improvement in the character of surface works than was noticeable even a decade ago. These signs point to an increasing faith in the permanency of the mining industry, which is becoming to be recognized as the real basis of our national prosperity. Twenty-five years ago it was thought that if the surface plant of a gold mine would endure five or six years that was as much as could be expected of it. Plants erected under similar conditions to-day are likely to last twenty or thirty years, if not longer, under proper care, for in the constructive feature the makeshift has given place to the substantial and enduring.

## Equipment and Longevity of Mines.

There are those who question the advisability and good business policy of operating a mine to its fullest possible extent. This is a question for careful consideration. A mine may easily be overequipped, if this expression may be used, if its resources are limited, or known within a reasonable approximation, as is sometimes the case where there are no extralateral rights, and the amount of material and value per ton of the mineral deposit below is known.

Development of a mine may be carried to such an extent as to make it possible to extract all of the available mineral in a few months, but it may be that the cost of plant to handle and treat successfully this large output would be so great that no net profit would result from the operation. A mine may develop a million tons of ore worth \$10 per ton, representing a gross value of \$10,000,000, and, under ordinary working conditions with plant worth \$1,000,000, pay a net profit of, say, \$4,000,000 by working 500 tons daily; but if the plant be increased at the expense of \$4,000,000 more, so that 2000 tons may be worked per day, the additional cost of plant would be at the expense of net profit, which would then be about \$2,000,000 instead of \$4,000,000, presuming that the cost per ton is somewhat lessened. To this should be added the increased interest on the more rapid production, but this is offset to some extent by increased interest on investment, and it is clearly evident that when the mine is exhausted the \$3,000,000 plant is worth little more than it will bring for old junk, unless the owners have another mine where the machinery, if in good condition, may be again used. The argument is sometimes made that "it is contrary to the best business policy to exhaust too rapidly the resources of a mine, or of a district, besides which something is due to those who make their homes about the mine and engage in commercial enterprises." This latter sentiment is, however, seldom given commercial consideration. Mining is carried on mainly in the interest of those whose capital is invested. The ethical idea that those who take up their residence about a mine, either being employed, or in business there, because of the existence and operation of the mine, are to be thought of in connection with economy of the mine's operation meets with small favor from those who are financing the operation. There is nevertheless the possibility that a mine may be too elaborately equipped and too vigorously worked to secure the greatest net result to the owners, as indicated above. The nature of some ore bodies is such that rapid extraction is essential to the greatest economy. Some of the bonanzas of the Comstock Lode, at Virginia City, Nevada, were of this kind—a mass of friable, crumbling ore which had to be extracted quickly to secure the best results.

Mines operated under the patronage of a Government are usually worked in a leisurely manner, as compared with private enterprises, but no one claims that the greatest profit results from these operations. It seems rather to be a paternal policy of the Government to give long life to the mine, and to extract all of the minerals contained in the ore which are of economic importance, regardless of the profit or loss proposition. This is not the policy of corporations and private companies, nor can it ever be, so long as mining is carried on with a view to securing the greatest possible profit in the shortest possible time.

## Adoption of a New Process.

When new metallurgical processes are to be introduced on a commercial scale, it is important that all the details be worked out by the inventor prior to making an expensive installation; but this, unfortunately, is not always done. In such event the company's plant becomes a school for experiment, not only for the perfection of the chemistry of the process, but also for evolution of a satisfactory and economical mechanical means to apply it. Often the estimated expense runs far in excess of the amount believed to be sufficient, and for this reason ample funds should be available, or all that has been done may be lost. Sometimes it occurs that after a plant has been installed its defects are realized, and it is seen that had a different course been pursued success might have resulted; but the funds are exhausted and the process is condemned, when a more fortunate application of the ideas might have brought success. It sometimes pays better to defer the construction of a plant until the fullest investigation proves that the proposed change can be made to advantage. In some instances the chemistry of a new process has been fully settled, but the details of the mechanical portion of the process have not been given sufficient consideration. The engineer engaged to review the proposed installation fails to discover this important fact until too late. The several devices are found to be crude and fail to properly perform the functions which they were expected to perform. Such experience stands as an example of the need of care in installing innovations which have not been worked out to a successful conclusion. Innovations are not to be discouraged, for metallurgical science as it exists to-day has been built up on innovations and upon the ruins of disappointed hopes. If no innovations are attempted progress would be slow and science would come to a standstill. What is required is careful, painstaking investigation and the proof that any proposed change can be made to advantage, and that the new invention—whether machine or process—will do what is claimed for it.

AMONG the first educational institutions of the country to take up the important matter of secondary technical education is the Colorado School of Mines at Golden in that State. At a recent meeting of the board of trustees of that college, it was decided to adopt a scheme which shall be operated in connection with, but independent of, the under-graduate and post-graduate courses of study for the benefit of miners. The course shall not exceed one year in length, and is intended especially for miners, mill foremen and metallurgical assistants, and shall be open to bona fide residents of Colorado, who are between the ages of 16 and 35 years. The requirements are chiefly the possession of an English common school education in the fundamental branches. The need of a higher and more comprehensive education among the assistants to the technically educated superintendents of the various branches of mining and metallurgy has long since been realized, and it is with a view to meeting this demand that the innovation here mentioned is to be made in the Colorado School of Mines. Ordinarily the miner and millman gains his knowledge through years of practical experience, but the need of hastening the acquisition of this necessary knowledge has led to the adoption of this very sensible plan. It is not claimed or thought that the student will, at the end of his course of one year, have learned all that can be learned, but, with a view to specialization, it is believed that he can acquire much of value to him and to his employer along the special lines which he shall elect to study. There has been a tendency in this direction for some years past, which has found application in the various correspondence schools. This newer idea brings the student into personal contact with his instructors and it will without doubt be well patronized by the men whom it is intended to benefit.

A NEW phase in industrial troubles in New South Wales, Australia, is reported by recent press dispatches. A number of miners and trammers struck in the coal mining district of Newcastle. They were arrested and formally charged with unlawfully refusing to work. Some of the trammers returned to work at a 10% reduction in wages.

## CONCENTRATES.

THE conveyance of a mining claim containing the apex of a vein conveys also the extralateral right.

THE function of the tightening pulley is to maintain an equal tension on the belt, and it also obviates the necessity of frequently taking up the slack as the belt stretches.

THE direction of a rope drive may be changed by interposing a pulley or sheave at the point of divergence, but usually the shafts of the principal pulleys of a rope drive are parallel and the pulleys are in the same plane.

A MILLSITE may be located by a citizen of the United States on the non-mineral public lands, but it is not necessary that such millsite locator have also a mining location in connection with the millsite. A site may thus be taken for the location of a custom mill or smelter.

WHERE the dump is settling rapidly at the front and there is danger of the car getting beyond the control of the trammer, accidents may be prevented by providing a rope supplied with a hook at one end. The rope is tied to a sleeper beneath the track and the hook made fast in the wheel frame of the car. It may then be dumped without danger of going over the dump.

THE mining laws of Arizona, passed in 1891, require that within ninety days from the date of making a mining location the locator shall sink a discovery shaft in the claim to the depth of at least 10 feet, or deeper, if necessary, until mineral in place shall have been exposed. The California law has no such requirement. In Montana a shaft 10 feet deep must be sunk within sixty days of the date of making location.

FEED WATER HEATERS are of various design and cost. The simplest are those which utilize the heat of the exhaust steam in heating water before it is pumped into the boiler. It is done by passing the exhaust through a chamber containing the water. A well-constructed heater of this type will bring feed water to 200° F., which effects a large saving of fuel. Such a heater can be made at small cost and soon pays for itself.

WHEN application has been made for a patent to a mining claim, the applicant must continue to perform the annual assessment work according to law until after the period of publication. If, pending the patent proceeding, the applicant fails to perform his annual labor, the ground becomes subject to relocation by others; but after the period of publication has elapsed, such relocater can not inject himself into the patent proceedings.

A MINING claim located in California, at any time during 1904, requires no assessment work during that year, as there is no local law requiring a stated amount of work as a part of the act of location (which some of the States require), and a claim located in 1904 is not subject to relocation January 1, 1905, nor until December 31, 1905, and not even then if the work of assessment has been begun and is actually in progress for the year 1905.

A CONVENIENT way to heat water for the change room is by placing a series of return pipes in the furnace or stove which heats the dry room and connecting these pipes with a tank of water in the upper part of the building. The water in the pipes within the stove is heated and rises to the tank above, cold water taking its place. A pipe may be taken from near the bottom of the tank and carried along the line of washing sinks for use of the men.

A NUMBER of small steel tools or other pieces of steel may be given a uniform temper by placing them in bone ash in a receptacle of proper construction and heating them in a furnace supplied with petroleum blast. All are given the same degree of heat and all are removed at the same moment, and may be tempered in the same manner. The only thing to guard against is the difference which may arise from the possible varying size of the several pieces.

IT is economy to lay the track as close to the face of the drift as possible. After clearing up, the track should be placed in position and a floor of lagging or plank laid for the broken rock from the next round to fall upon. Lagging is sometimes broken by the blasting, but on the average, much time is saved by providing this floor. Short pieces of track should be provided and when advance enough is made a full-length rail may be substituted for the short sections.

THE "mustard" or clay-like gold found in some of the mines of the Coolgardie district of Western Australia has been found to be metallic gold of a sponge-like character, composed of innumerable microscopic globules, threads and filigree, cemented together. It is dull and lusterless when taken from the mine, but if a knife blade be passed over it the metallic luster is at once evident. A similar occurrence of gold has been noted on Bullcreek, in Mariposa county, Cal., where good sized nuggets, which would weigh \$6 to \$12 if of gold of the ordinary kind, are found to contain but \$2 or \$3 owing to their peculiar cellular

structure. It is thought that this is due to the removal of some mineral formerly intimately associated with the gold, probably tellurium. At one time it was thought that these occurrences presented allotropic forms of gold, but the former theory is the more tenable.

THERE are machines made for bending rails, which operate with a heavy thread, like a jack. They are easily portable and may be taken underground. Track rails are usually adjusted by spiking one end and prying the rail over with a bar to the point required and spiking it there. The machine mentioned is useful for bending heavy rails—35 pounds per yard and heavier. Underground rails should be at least 12 pounds per yard for ordinary use, though if the mine be dry so that ties will stay where placed, 8-pound rails may be used if the cars are not too large. On the surface it is advisable to use 16-pound rails.

QUICKSAND has been solidified sufficiently for the purpose of excavation by injecting cement into the mass. It is done by driving pipes into the quicksand from 4 to 8 feet apart, and then by connecting a pump with alternate pipes and pumping water into the pipes under pressure, which establishes a circulation between the water pipes and those left open, as sand is displaced by pumping, cement grout is pumped in to take the place of the sand. When the grout appears in the open pipes the latter are capped and the water pressure is continued, forcing the cement into the surrounding sand. It is then left to set. The pipes are then raised a few inches and the process repeated. It is said to work better in coarse sand and gravel than in fine quicksand. In the latter the freezing process is said to work more satisfactorily.

WHERE convenient to place them, well constructed switches are superior to turntables, such as are ordinarily built underground. A good turntable is all right, but in the desire to economize they are often poorly constructed, and require the services of two men to turn a loaded car on them. A turn sheet is better than a poor turntable. Poorly built switches are no better than a poor turntable. The time lost in replacing a loaded car which has jumped a poorly built switch would have built a good one. Switches should be so made that they may be quickly adjusted, and easy of access for repairing and to free them from muck. The pin, which holds the movable pointed rail, should be strong and set in a solid plate, but not upset below the plate, for it should be so arranged as to be quickly taken up if necessary.

It is presumed that the owner of a mine will keep the mine clear of water in his own interest, but he is under no obligation to do so. The work of development and mining must be done in such a manner as to cause no damage to adjoining property, but if at any time the closing down of his mine, or a portion of it, permits water to rise and flow into an adjacent mine the owner of the idle mine cannot be held responsible for any damage or increase in water from this cause. The owner of a mine, for the purpose of protecting himself from an inflow of water, may erect a dam or other structure on his property for the purpose of restraining or diverting the water, subject to the limitation that such dam, bulkhead, or other structure, has no effect which will be detrimental to the property of the adjacent owner, and which damage would not have occurred were it not for the dam.

BLEACHING POWDER is also commonly known as chloride of lime. It is soluble in about 20 parts of water. When brought into contact with sulphuric or hydrochloric acid it gives up its chlorine. With the sulphuric acid, the sulphur unites with the lime to form calcium sulphate, leaving the chlorine free. It is used in the barrel chlorination process. In making the charge it is customary to first charge the "bleach," as it is called, which is followed by the ore, which completely covers the bleaching powder. Then the water and acid are introduced, the barrel quickly closed and the cover secured. The barrel is then retorted, which results in a thorough admixture of the several ingredients of the charge. The chlorine is liberated, as above indicated, and attacks the gold present in the ore. The process was quite extensively employed some years since at Deadwood, S. D., in the treatment of the telluride gold ores of that district, but has since been superseded by the less expensive cyanide process. There are ores, however, which may be successfully treated by the barrel chlorination process which are not readily amenable to cyanide treatment.

ORES being roasted prior to pan-amalgamation require a less careful roast than those which are to be leached or amalgamated in wooden barrels. The grinding of the muller in the iron pan and the chemical reactions taking place overcome to a certain extent the defects of incomplete roasting, but it is always advisable to roast the ore carefully. It is not customary to add salt in roasting ores containing an appreciable quantity of gold when the roasting is done in an open furnace like a reverberatory. A reliable method of determining the loss of gold and silver in the roasting of large amounts of ore, is to dry, weigh, sample and roast a quantity, from one to ten tons. After cooling, weigh and sample again. It may weigh more or less than before roasting, depending on the original character of the ore, the amount of salt used, etc., and the manner in which the roasting was

done. The assay of the unroasted ore, with reference to its total weight, will give the value of the ore before roasting, and the same method on ore after roasting will give the value after roasting, and the difference will represent the losses by volatilization and dusting. To make this test dependable the furnace must be thoroughly cleaned, both before and after the roasting. With a furnace of proper construction a portion of these losses may be recovered in the dust chamber.

NATIVE ARSENIC occurs sparingly, but the compounds of arsenic with base metals and with silver are numerous. The most common of the arsenical compounds found in nature is mispickel, or arsenical pyrites (FeAsS), and is usually regarded as the equivalent of pyrite, in which one atom of sulphur has been replaced by one of arsenic. Arsenical ores containing gold have been successfully treated by amalgamation, followed by roasting, during which arsenic oxide passes off in white fumes, and is condensed in chambers and the subsequent treatment of the roasted ore by the bromo-cyanide process. It is not always possible to tell without experiment whether an arsenical gold ore is amenable to this process without trial. The process outlined above is that practiced at the Del Oro mines, Hamilton, Ontario, Canada, and is eminently successful there.

EVERY MINE should be provided with adequate fire protection and the workmen drilled in the use of fire apparatus, both above and below the ground. The best fire protection is afforded by distributing hydrants at numerous places easily accessible, and provided with nozzles. The pressure, where possible, should be at least 200 feet—and more is better. This permits men to fight fire at a considerable distance and dispenses with the necessity of a hose. The nozzles should form a portion of the hydrant and be so arranged as to be pointed in any direction. The whole affair may be made of 3-inch and 4-inch pipe, the nozzle being of 3-inch pipe drawn down to an orifice of the proper size, and supplied with a thread at the other. The stand pipe may be made of 4-inch pipe, having an elbow at the upper end. Into this should be screwed a short nipple, to which is attached a second elbow, and into the latter is screwed the nozzle. By making the pipe connections loosely, so as to allow of easy freedom of movement, the nozzle may be elevated or depressed, and turned either right or left, at will. The controlling valve should be a straightway gate set in the standpipe, and the apparatus should be frequently tested, to know that it is always in good working condition.

THE practice of sweating amalgamated mill plates, as carried on at a West Australia mine, is by covering the plates with gunny sacks and turning steam in between the plate and the bags. This is continued for an hour or more, when by which time the amalgam is so soft that it may be readily removed with an iron scraper. The plates are not injured by the process—on the other hand, are softened and annealed by it and rendered better for the purposes of amalgamation. If the coating of gold is thick, it peels off in good-sized scales. It is more easy to remove a thick than a thin layer of amalgam. Overheating plates by means of direct application of fire is considered injurious to the plate. After treating by sweating, as above described, the plate is wet with strong hydrochloric acid and kept covered with it for twenty-four hours. A mixture of equal parts of powdered ammonium chloride and nitre is then spread over the plate and it is then gently heated. The dressing melts and appears to work its way beneath the gold; when the heat has raised until the plate is red hot it is set aside to cool, when the gold may be stripped off into a vat or tub. Where the amalgam is thin, patches of gold will often remain. When it is no longer desired to use the plate, it may be heated red hot and sprinkled with flower of sulphur, which causes the gold to form in blisters on the surface of the plate, when they may be removed. These measures are only justified when mill work is to cease for a considerable time or permanently.

MANGANESE OXIDE (MnO<sub>2</sub>) is often found associated with ores of gold and silver, particularly the former. Noted instances are Butte, Mont., Leadville, Colo., and Tombstone, Ariz. The action of manganese dioxide on mercury is not well understood and its evil effects are often the cause of much annoyance, notably in pan mills. It is thought by many that in some manner nascent oxygen is given off from the black manganese oxide, and this in some manner affects the mercury. In pan mills caustic lime is often added with good effect, and it may be that a similar result might be obtained by adding quicklime to the mercury in a plate mill. In some mills concentration before amalgamation has been found to give better results than are obtained in the usual practice. In concentration before amalgamation much of the deleterious mineral present—usually manganese oxide, molybdenite or graphite—is washed away, and the gangue and precious metals, relieved of these substances, amalgamates more readily. In other cases concentration alone has been found to result in a saving of a higher percentage of the values than could be obtained by amalgamation alone in the presence of manganese, graphite or molybdenite. In the treatment of some silver ores by pan amalgamation process, where much base metal is present, the addition of a small amount of manganese oxide has been found to have a beneficial effect, producing a higher-grade bullion than was otherwise obtainable.

## The Mother Lode in Amador County, Cal.\*

NUMBER II—CONCLUDED.

Written for the MINING AND SCIENTIFIC PRESS by W. H. STORMS.

Heavy gouges, often many feet in thickness, indicate more clearly than any other physical feature the extent of these movements, which must have continued throughout a long period. Some mines show evidence of several periods of such movement. Quartz veins have been formed and subsequent pressure and movement have fractured the solid quartz into thousands of fragments of all sizes, from fine granular material to boulder-like masses, often including more or less of the black slaty material. In most instances infiltration of silica has cemented these shattered zones, reforming solid veins, which, in some places, are over 100 feet in width. Very large bodies of this description occur in the Wildman mine at Sutter Creek, and also in the Keystone mine at Amador City.

In the town of Sutter Creek and vicinity there has been much dynamic disturbance. Wherever the slaty rocks can be seen on the surface they are found contorted, folded and faulted in the most perplexing manner. This condition is also in evidence in the underground exposures of the Wildman mine. Between the 800 and 1200-foot levels, particularly, the country rock, with its included veins, has been faulted and folded in a way that renders the operation of the mine unusually difficult. In some places the normal dip has been changed from east to west. Large veins of good ore are found abruptly cut off and their continuation has never as yet been rediscovered. In one instance the unusual occurrence of two pay shoots divided by a stiff putty-like gouge 3 feet wide has been worked. This gouge also contained gold and was sent to mill. In the Kennedy mine a black clay slate gouge was mined which was rich in gold.

To complicate matters the vein splits near the north line of the Wildman, the east branch running through the Mahoney into the Belmont claim and beyond, presumably into the Mutual mine, probably forming what is there known as the Mexican vein. The west branch runs through the Mahoney into the Lincoln mine adjoining, through which it courses with a fairly uniform strike. The vein splits into several minor branches on the slope of a greenstone hill, several hundred feet north of the Lincoln shaft, and, as far as known, these branches never reunite, nor has it been possible to trace the Lincoln vein, in its individuality, beyond the south slope of this hill of massive diabase.

This is a condition which has attracted much attention locally. The Lincoln vein was one of the richest worked in this county in the early days of mining on the Lode, and to the depth of 350 feet, or thereabouts, formed a strong banded vein of high-grade gold ore, from which large profits were derived. At about the depth indicated, however, a fault striking nearly with the vein and having a somewhat flatter dip, cut off the pay shoot, and although extensive development has since been made, the downward continuation of the original vein has never been identified.

That this fault was a normal one is indicated by the fact that all of the slates and schists occurring to the eastward of the fault plane have the normal east dip, common to the region where not disturbed, while all rocks (schists and slates) to the westward of the fault have a decided dip to the west, as though the entire country had been flexed eastward and downward by the settling hanging wall rocks. The indications are that this fault is much more extensive than at first may be supposed, but, owing to the extreme irregularity of the occurrence of slates and schists, with their very numerous minor faults and folds, it is impossible to even approximately estimate the amount of the throw of the fault. The work now being done by the Wildman company through the Lincoln shaft may throw some light on the perplexing problem. It is possible that the fault in depth may have merged with some pre-existing vein fissure, but this is not known to be the case.

The Lode is found in strength to the northward of this region of disturbance, in and near the town of Amador City, in the South Spring Hill and Keystone mines, but it has been impossible to trace a direct connection between the veins of the Lincoln mine on the Sutter Creek side of the divide and those of the South Spring Hill mine on the north side. An exposure of rocks is found along the county road between Sutter Creek and Amador City, but where the black clay slates and greenstone schists are found in contact, and where the miners of this region would expect to find the vein from experience along the Lode to the northward or southward, no sign of a vein is seen other than an occasional bunch of vitrious white quartz, with which have been found occasional pockets of gold in the Talisman and Wabash claims, and also, I am informed, in the North Star mine. There is, however, no indication of gouge or a banded, regular vein—the characteristic features of the Mother Lode veins at contact.

A few hundred feet to the west and northward of this exposure occurs the great system of veins and fissures of the Keystone mine which have been developed by over 10 miles of level and shaft. The workings are about 1500 feet deep on the vein, and extend

from the South Spring Hill to the northern limit of the property. There are several nearly parallel veins in the black slates of the west country; a large brecciated vein, or lens of amphibolite schist and quartz, which, in places, is 150 feet in width, and a hanging wall fissure noted as a producer of pockets. To attempt to describe the Keystone mine in a manner which would do justice to either the mine or the person undertaking so great a task would require a good-sized volume, so it may be said briefly that it consists, as previously stated, of a series of veins of approximate parallelism in both strike and dip. The heavy gouges, the banded, massive and brecciated veins, all are here present in typical form. Southerly these veins extend into the South Spring Hill and South Keystone properties, having been extensively developed in the former, the latter having as yet only superficial workings. The strike of this series of veins through the South Keystone, if followed closely, will carry them to the westward of the Lincoln mine at Sutter Creek, unless the formation or the veins themselves swing to the eastward in their southerly course. If this occurs it is not as yet recognized as a fact, and it is not indicated by surface exposures and numerous open cuts.

It appears as though the massive greenstone hill north of the Lincoln mine has acted as a barrier, as it were, to the formation of a continuous fissure northward from the Lincoln mine, and that the stress producing the fissures, being insufficient to disrupt the massive, tough diabase, caused the fissure to split into a number of branches which died out in the hard intrusive mass of greenstone. As the disturbing forces were not local, but rather of orographic character, the stress was sufficient to produce extensive fracture and movement in the slates and along the contact of slate and greenstone, to the northward and west of the diabase hill, and in these fissures were formed the veins now developed in the several mines extending northward through the South Keystone, South Spring Hill and Keystone mines. On the North Star claim a shaft has been sunk 1000 feet deep and a vein cut in a crosscut run west from this shaft. Beyond the Keystone the fissure system extends in essentially unbroken lines, through the Bunker Hill properties, and beyond into and through the Hazzard and Fremont Consolidated properties. Great masses of quartz characterize this portion of the Lode and outcrops upward of 100 feet in width may be seen on some of the mines. In the underground workings of the Fremont Consolidated mines are similar great lenses. Each mine has characteristics peculiar to itself, and yet, on the whole, they each have features, both structural and geological, peculiar to all.

The Lode continues northward as a series of veins possessing the same characteristics as those previously described, and in the vicinity of Plymouth another great mine was developed—the Plymouth Consolidated.

There is nothing in the topography of the country to indicate the presence of rich mines as compared with those of lesser merit. Among the great mines the Consolidated Eureka at Sutter Creek, and the Keystone at Amador City, have somewhat similar surface conditions, but underground they are very different as indicated by the description of each as previously given. This similarity of surface contour has been noted by some, but it is due to erosion under similar conditions—the soft slates along the line of fissuring cutting away faster than the hard greenstones. Such topographical features are no index of value in the mines themselves. At the Kennedy, Argonaut and South Eureka, the rocks have been protected from erosion, as previously stated, by the ancient river channels which formed in the valleys crossing the Lode in Pliocene time. Recent erosion has modified this topography, and, in some instances, the valleys have become the hills, and where there was solid rock the more recent streams have carved out for themselves new canyons, and it may be safely said that in many instances the topography bears almost no relation to vein structure on the Mother Lode, and certainly none to the value of the mines.

At the Plymouth Consolidated mines the country is nearly flat. Northward from Plymouth the Lode again, apparently, has a direct influence on the topography of the country, for it has undoubtedly been responsible for the canyon of Indian creek. Beginning in a shallow, amphitheater-shaped valley at Plymouth, it gradually deepens northward until the surrounding hills rise more than 1000 feet above the stream. The western and eastern hills are of hard greenstone, while the canyon bed is largely soft clay slate and amphibolite schist. Numerous springs mark the course of the Lode along the west side of the valley, and several gold-bearing veins are known, and some development work has been done on them. The Illinois claim is on one of these, where a vein of white quartz in the creek bed prospects well. Heavy gouges, with brecciated quartz, mark the position of some of the more important fissures in this vicinity, but for some reason very little prospecting has been done for a distance of four miles between Plymouth and the Rhetta Consolidated mines. This latter has extensive development, and several veins of good gold rock have been developed in the property. After crossing into El Dorado county the Lode is undoubtedly responsible for the deep canyon which follows it for a distance of about 10 miles to the German mine,

the cause being, as previously stated, due to the easily eroded fissured clay slates between great masses of harder greenstone. In this part of the Lode, and, in fact, from the vicinity of Sutter Creek, the ancient river channels have apparently had little or no part in influencing the topography of the country, as far north, at least, as the vicinity of Placer-ville, in El Dorado county.

## Electricity for the San Juan Country of Colorado.

An important industrial enterprise to be inaugurated in the San Juan country of Colorado this year is that of the Animas Canal, Reservoir, Water, Power & Investment Co., located on the Animas river, 20 miles below Silverton, at the mouth of Cascade creek. It consists of a large plant for the generation of electrical power to be distributed to the mining districts of San Juan, Ouray, Hinsdale, San Miguel and La Plata counties, furnishing light and power to cities and mines. It is estimated to cost, when completed, \$5,000,000.

Work was begun on the construction of the power plant in June, 1903, and the initial plant will be completed by July 1 of this year, ready to deliver electric power to the Silverton district and the city of Durango. The work finished on the initial plant consists of a dam and headgates in Cascade creek,  $3\frac{1}{2}$  miles of flume 6 feet deep and 8 feet wide, a crib dam at the reservoir site 50 feet high and 700 feet long, and a foundation for the power house, 3 miles above Rockwood. Poles have been set from the power house 28 miles to Silverton and 20 miles to Durango. The wires will be strung early the coming season. The work yet to be done on the initial plant by July is the completion of the power house and the building of a 2-mile flume from reservoir to power house. The latter has all foundations of concrete, and the structural part is being built of brick and steel. The reservoir dam is of timber cribs, drift bolted together, filled with rock and made tight on the upstream side by three thicknesses of 3-inch plank. The reservoir is  $3\frac{1}{2}$  miles long and 1 mile wide at its widest point. The pipe line from the reservoir will be 34 inches in diameter at the power house and 44 inches at the intake. The fall is 997 feet. Machinery first to be installed consists of three 1000 H. P. generators, directly connected with two 4000 H. P. Pelton water wheels. Accommodations are provided for two extra generators, making 12,000 H. P. possible. Six thousand horse power will be installed within the next ninety days. The cost of the initial plant will be \$750,000. It is expected to eventually increase the capacity of the establishment to 40,000 H. P.

When the initial plant is ready for operation wires will be strung to Durango, Silverton, Telluride, Ouray, Lake City and to mines all over the San Juan country. The company guarantees to furnish electricity for all purposes required at a cost to consumers not to exceed 75% of what they have heretofore been paying.

The principal offices of the company are at Durango, with a branch office at Indianapolis, Ind. The officers of the company are Dr. H. Jameson president, T. N. Harden vice-president, P. Gray secretary, B. F. Schmid treasurer and general manager, H. T. Henderson chief engineer and general superintendent, A. H. Firey chief electrician.

## Taviche District, Mexico.

This district is about 250 miles south of the city of Mexico. Its altitude is 5000 feet and its climate mild and salubrious throughout the year. It is a region of "perpetual spring," although within the tropics, says a writer in the Mexican Investor.

The natives live in huts and houses of cane or reed, like the villages of Central Africa. They are poor, but being very good-natured, contented and cheerful, enjoy life. Wages are very low. Miners and mechanics earn about 40 cents gold per day; laborers (peons), about 25 cents a day; a good native house-keeper and cook, 80 cents per week. All native products are cheap. Turkeys, for example, are sold at the market for 20 cents gold a piece.

The mines were worked from prehistoric times by the Aztecs or Toltecs and their unknown predecessors. Despite their antiquity these mines are shallow. The older work was done by the firing method. A fire was kept burning against the face of the ore to be extracted until, for a few inches depth, the ore was cracked. Water was thrown on the hot rock to assist the cracking and so a few pounds were broken loose. With depth the heat and smoke prevented the miners from maintaining more than a single fire at a time. One can walk along the outcrops for hundreds of feet and see the walls of the vein still standing, from which the ancient miners with infinite pains and perseverance extracted the ore. The veins are from 3 to 12 feet wide. The country rock is eruptive.

More modern methods have been adopted only within the last twenty years. The district is now fairly productive. Several mines within the past five or six years have records of shipping \$4,000,000 to \$5,000,000, Mexican, worth of ore. Americans have

\* See illustration on front page.

recently purchased about a dozen producing mines and are extracting ore on a scale hitherto unknown in the district.

Little water is so far encountered. The ore hitherto has been raised by large horse whims, called "male-cates," sometimes, by attaching three or four arms, six or eight mules could be used or worked there at a time.

The Mexicans are noted ore-sorters and reduce the ore to pieces no larger than 1.5-inch diameter before rejecting it. For this work they receive the equivalent of from 12 to 24 cents United States money per day. In one mine thirty-seven days' labor was required to sort out one ton of shipping ore. The value of the crude ore averaged about \$36 gold; that of the rejected waste, \$12 gold; shipping ore, about \$180 per ton.

## The Center Star Mine, Rossland, B. C.\*

NUMBER II.

Written by L. H. COLE.

**DRILLS USED.**—Most of the drills used are of 3½-inch diameter and 6-inch stroke—Rand drills of the Little Giant type. They are set up, where possible, on columns, which can be braced to the sides of the drift or to the floor and the back. Where the use of a column is impossible a tripod is used. The air compressors are also of Rand make.

Cross bits are welded to round shanks, which vary in length from 18 inches to 10 feet. One shift of eight hours dulls about thirty bits to each machine.

A round of holes for drifting in this mine generally consists of ten holes arranged as follows:

Two back holes, three break holes, three cut holes, two lifters.

If the work is heavy a couple of holes may be added, one more lifter and one more back hole. The length of the holes varies from 5 feet to 7 feet.

The back holes are inclined at an angle of about 30° to the horizontal.

The next row of holes, called breast holes, is drilled slightly off the horizontal, just enough to hold water. They break down the portion immediately below the rock in which the back holes are placed, so as to relieve these upper holes.

Below the breast holes is another row, called cut holes, placed so as to run down at an angle of about 45°. They remove the central portion of the rock so as to allow the other holes to break well.

The two bottom holes or lifters are drilled in at an incline downwards so as to form a wedge with the cut holes. Their object is to keep the floor on a level.

The side holes in each row are inclined either to the left or to the right, according to the side they are on, in order to keep the walls at an even distance apart. Where the drift is required to turn either to left or right, all the holes are inclined in that direction.

For raises or winzes the holes are so placed that when the center cut holes are blasted a free area is left for the other holes to break into. Eighteen holes is the usual number for a round, three in each line.

An exactly similar round is used for sinking, with the exception that the center holes are inclined more towards each other so as to give more breaking power. The average length of the holes is from 6 feet to 8 feet. For shaft sinking a great many more holes are used, as the area to be broken is generally larger.

The holes for stoping are placed so that the fullest breaking power of the charge can be utilized, and are placed horizontally in rows, one above the other. The higher holes are a little shorter; all are water holes.

When possible all blasting is done at night. The hours from 1 A. M. to 7 A. M. are set apart for this, and two men do the blasting for the whole mine. By this method the mine is free from gas and smoke for the morning shift.

The 60% powder is only used to break boulders, or whenever hand drilling is used for timbering holes.

The average charge for a drift round (ten to twelve holes) is from 90 to 100 sticks, or about 45 pounds.

The shortest fuse is timed to burn six minutes, giving the men time to get to safety.

In drifts the cut holes are fired first, then the breast holes and lifters, and last of all the back holes. In raises, etc., the center holes are first fired, then the following rows in order.

Stoping holes (horizontal) are fired one row at a time. The men then charge the next row above and fire that. They continue this until the whole round is blasted. Similarly in shaft sinking, the center holes are blasted and the muck is cleaned out before the next row is fired.

**MUCKING.**—When the working place is clear of smoke the mucking of the ore begins. The muck is loosened and shoveled into small cars, which are trammed to the shaft station by men. No horses or mechanical power are used underground, with the exception of on the second level. Here a small sta-

tion hoisting engine is used, which pulls out eight cars at a time. It is impossible for this to be done by men, as there is a heavy grade in the drift by reason of the drainage being towards the mouth of the tunnel.

The rails are of 16 pounds per yard, which are spiked to ties placed 2½ feet apart. Track laying is kept well up with the work.

The curving of all rails is done underground as required.

The car used stands 2 feet 11½ inches from top to rails, and holds 16 cubic feet—approximately 1 ton.

**HOISTING.**—The main hoist in the mine has two drums, each 6 feet by 3 feet, with a capacity of 1700 feet of round steel rope of ¾ inch diameter. The average winding speed is 800 feet per minute, with a maximum of 1000 feet per minute.

The engines are 14-inch by 18-inch stroke, with reversing gear. A friction clutch is attached, permitting of either drum being run independently, so that hoisting may be carried on at the same time from different levels. The round rope is prevented from cutting the foot wall timbers by rollers placed on the wall plates at intervals.

The skip runs on a 30-pound steel rail spiked to the foot wall plates of the shaft. The shaft guides are chiefly for safety purposes, so that the safety clutches can grip them in case of accident.

The weight of the skip is 2400 pounds and of the ore 4000 pounds; total weight hoisted, without rope, 6400 pounds.

The skips baul with detaching hooks, so that in the case of an overwind the rope is detached and the skip hung in the head frame.

When a winze is being sunk a small temporary hoist is generally used and the muck, etc., is hoisted in a bucket running on skids, and is dumped automatically into cars when it reaches the level.

**TIMBERING.**—On account of the solidity of the rock, timbering is not required in ordinary drifts and cross-cuts. In stopes and raises stulls and lagging are used extensively, but when the stope becomes too wide (15 feet is about the limit) square sets are adopted. Square timbers are also used in the shaft. The timber is supplied to the mine as:

Square timber: 10x10-inch square by 16 feet long.

Planks: 3 inches and 4 inches wide by 16 feet long.

Stulls: logs varying in diameter from 10 inches to 25 inches with the bark removed and cut into lengths of about 16 feet.

Lagging: small, round timber left in the rough and in 16-foot lengths. Tamarack is generally used.

Adjacent to the framing shop, and connected with it by tracks, is a commodious timber yard. The timber is hauled along the road on the upper side of this yard, and from the wagons it is rolled down skids and piled, being brought into the framing shop on trucks. A swing saw is used for cutting the timbers to the required lengths, and the spare timbers are framed by the timber framing machine. From the framing shop the timbers are trammed to the collar of the shaft as needed. For lowering the timber into the mine the ordinary skips are generally replaced by a special timber skip.

In the shaft the sets are run at right angles to the dip, but in the square set stopes the floors are laid level. On the other hand, in the narrower stopes the stulls are placed approximately at right angles to the walls.

The timbers are firmly wedged into place by wooden wedges. On top of these is placed the lagging, so as to form a solid floor. The flooring used in the square sets is 3-inch and 4-inch planking.

**PUMPING.**—The water encountered is comparatively small in amount and is non-corrosive. Three pumps—one on the fourth level, another on the eighth level and the third in the sump—suffice to cope with all the water.

A large pump, to be run by electricity, is now being installed at the sixth level station, which will do the pumping for the whole mine.

**VENTILATION.**—The mine is provided with a blower, having a 14-inch delivery pipe. It runs about eight hours per day and supplies 150,000 cubic feet of air per hour. It is driven by a 10 H. P. induction motor. The blower is reversible and can thus be used either to force fresh air into the mine or to exhaust the foul air.

There is more or less natural ventilation up and down the shaft, due to its connection with the tunnels. When stopes or raises extend from level to level a certain amount of ventilation is secured, but when these are not completed artificial ventilation is required. Much time is saved by artificial ventilation, as the smoke and poisonous gas generated by the explosion of the powder are quickly sucked out by the reversed blower, and the working place cleared so that work can be resumed.

**LIGHTING.**—The main shaft, stations and principal tunnels are lighted with electric incandescent 32 candle power lamps. The wiring for the mine lighting is carried down the shaft in an iron conduit with iron junction boxes at each station. The wiring is so arranged that the lamps can also be used for flash signals if needed.

**TELEPHONES.**—There is telephonic communication between all the principal mine buildings, and also between the lower mine workings and the shaft

house. The system is so arranged that no central exchange is needed.

Electric gongs are used for station signals, but pull bells are used to signal the skips.

**SURFACE SURVEY WORK.**—Except where very accurate work is required, the location of all mine buildings is done by the stadia method. If accurate work is to be done, a transit and band tape are employed; for leveling, an ordinary level is used.

**UNDERGROUND SURVEYS.**—In underground work the transit (reading to minutes) and steel tape are used entirely. Survey stations are set at convenient intervals in the mine, which are accurately located from a line down the shaft. The methods then em-

Surveying in the Center Star Mine, Rossland, B. C.

ployed are as follows: Stations are placed in the back of the drift, etc., by drilling 2-inch holes about 4 inches deep. Into each of these holes is driven a wooden plug, level with the back. Horseshoe nails, with a pierced head, are placed in the plugs to allow of plum bobs being hung from them. A brass tag with the number of the station on it is fastened beside each nail.

The advance is surveyed twice a month. It is taken up as follows: (See diagram transit set up at station 37); vernier set 0°, B. S., on station 33; a sight is then taken on station 81 and angle read. Angles are always read twice, by doubling, as a check. The elevation of station 81 is located, by means of a button set on plumb bob at 81, on a horizontal line from the transit. The horizontal distance between 37 and 81 is measured to the nearest hundredth of a foot, and contours taken, left and right, from the line. This operation is repeated at 81 and sight is taken to face of drift.

(TO BE CONTINUED.)

## THE PROSPECTOR.

In his search for valuable minerals the prospector often finds himself unable to comprehend what he observes in nature. He has his conception of what certain rocks should look like, basing his judgment on what he may have learned in some district where he had fairly good facilities for information. If he has learned what he knows of rocks in a region of sediments which have been little altered, he would not, perhaps, recognize rocks formerly familiar to him because of their alteration in a country where igneous rocks have been thrust into the sedimentaries, and where there has been more or less metamorphism. The familiar, comparatively soft sandstone has become dense, hard quartzite; the gray lime is now found altered to white or blue marble, or perhaps to a fine grained quartz, or to a rock largely composed of garnet. The soft gray shales may be changed to hard, fine grained jasper, or to slates in which there is development of unfamiliar crystals. These and many other changes the prospector must learn to distinguish and understand in order that he may prosecute his search with intelligence. He must learn to distinguish faults and their relative age; to tell a recent fault from an older vein; to know the difference between a vein and a zone of mineralization; to notice and understand folds and unconformities in the rocks, and many other things, all of which apply directly to his trade as a prospector.

The rocks from Bodie, Cal., are classed as follows: No. 1, felsite; No. 2, diorite-aphanite; No. 3 is a fine-grained phyllite or hydro-mica schist, containing a large percentage of small crystals of zinc blende. When scratched by a knife the streak leaves a luminous trail momentarily behind it. This has been called "luminescent sphalerite." It is a property not uncommon in zinc blende. No. 4 is a granular

\*Abstract Trans. Canadian Soc. Civil Engrs.

quartz ore. It contains finely disseminated pyrite. No. 5 is galena in a gauge of iron carbonate and dolomitic mineral; No. 7 is a fragment of rhyolite decomposed by surface weathering; No. 8 is a variety of opal, a hydrous silica.

The rock from Manila, P. I., is a much altered hornblende granite. The light colored scales are secondary mica resulting from the alteration of feldspar. If gold bearing, as stated, an effort should be made to locate the principal deposits or enrichments whether as chimneys or veins. If no veins or zones of mineralization are found, the probability is that the values will not be found to go very deep.

The rocks from Searchlight, Nevada, are: No. 1, iron stained limestone; No. 2, largely quartz in a brecciated mass. The indications are that this rock may have originally been limestone, which has been replaced by silica. It should be assayed for values in gold and silver.

The mineral specimen from Princeton, Granite county, Mont., is crystallized limestone (marble), in which is disseminated small grains of pyrrhotite, a magnetic sulphide of iron, sometimes containing nickel.

The rock specimen from Blackbird, Idaho, is very much altered and seems to have been originally a basic dike rock. It shows a slight efflorescence of copper carbonate, and considerable carbonate of lime. It may be that on sinking a shoot of ore will be found. This is not an easy matter to predict, however. Some prospecting should be done at greater depth.

The "red rock" from Patagouia, Ariz., is jasper the hard shining portion, and hematite (iron oxide) the soft portion. Occasionally rocks of this description contain gold and silver.

The three rock specimens from Yale, B. C., are: No. 1 is slate, apparently an ancient tuff, composed of alternating layers of volcanic debris and fine mud, latter probably derived from the wearing down of an older rock; No. 2 is a much altered rock, evidently a greenstone. It carries a large percentage of pyrrhotite, a little pyrite and still less chalcopryite. Quartz grains are abundant; No. 3 is an altered intrusive rock — granite or syenite — too much decomposed to identify. The rock contains cubes of partly altered pyrite.

The five rock specimens from Santa Ana, Cal., are: No. 1 is aplite, a micaless granite; No. 2 is syenite. The rock consists almost wholly of orthoclase feldspar and altered hornblende. A very small amount of quartz is present. This rock approaches closely the typical syenite; No. 3 is the ordinary granodiorite of California; No. 4 is fine granular quartz stained with manganese oxide. The green color is due to copper carbonate; No. 5 is granular quartz, with brown iron oxide. The transparent crystals are gypsum-calcium sulphate.

### Dewhurst Slag Ladles and Cars.

The Wellman-Seaver-Morgan Co., Cleveland, O., have sole American rights for the manufacture and sale of the Dewhurst slag ladles and cars, illustrated herewith. Hand tipping is done away with, the ladles being tipped by a pull of the locomotive on the tipping chain. There are no power cylinders, gears

end, one for hooking to the car and the other for hooking to the locomotive. This chain may be hooked to either end of the car, as required. The locomotive pulls away from the ladle while dumping. Hence, if the chain should break, the locomotive is not endangered, but will run away from the ladle instead of toward it. When the slag has been dumped the ladle rights itself by gravity, by merely backing the locomotive. A train of side-tipping ladles can be tipped in series by attaching the hook of each ladle to the car ahead of it. The end-tipping ladles are tipped by a direct pull of the locomotive from the opposite end of the car, the locomotive pulling away from car.

On all ladles a forged steel band is attached, running around the ladle slightly below the rim. By fixing the tipping point high on the ladle, the leverage is increased and the tipping process made easier.

Double trunnions are cast on each side of the ladle, being located slightly above the axis, so that the ladle will right itself from any point to which it might be tipped. Roller bearings are provided on which the trunnions rest.

The ladles are of special shape, to facilitate the stripping of the slag and skull. Hence, in dumping, the skull follows the molten slag, requiring no hand work for its removal. The whole of the work is handled by the locomotive and its crew. The ladle is cast in a single piece, and heavily ribbed on the outside to stiffen it and increase its strength.

Cars are built for standard gauge tracks, and are equipped with either four or eight wheels, as may be required. They are built in a variety of sizes, ranging in capacity from 70 to 280 cubic feet in side-dumping pattern, and from 70 to 210 cubic feet in end-dumping pattern, the 210 cubic foot car of each being their standard size. Further details will be furnished by the builders on application.

### Pacific Coast Water Powers for Electrical Operation of Railroads.

"The Use of Pacific Coast Water Powers in the Electrical Operation of Railroads" was the title of an interesting paper read before the Pacific Coast

was called to the wide-spread consideration now being given to the application of electricity as motive power to replace steam locomotives on railroads, reference being made to the large undertakings of this nature under way by the New York Central and the Pennsylvania Railroad Companies.

The advantages of electric traction over steam for the operation of railroads were considered under three heads, viz.: 1—Those appealing to the passenger and resulting in an increase of traffic. 2—Those pertaining to the centralization of power; and 3—The economies in first cost, maintenance and operating expenses.

Under the advantages to the passenger was mentioned the freedom from dirt and smoke, the universal cleanliness and the better ventilation and lighting of electric cars. Reference was made to the possibilities of obtaining higher average and maximum speeds with electric operation and to the greater tractive effort resulting from the increased weight on the driving wheels.

Under the advantages of a central power station the author spoke of the present-day limitations of the steam station and of the self-evident possibilities of obtaining power from hydro-electric plants. Particular reference was made to the conditions on the Pacific coast, where available water powers are distributed at frequent intervals from southern California to British Columbia. While but a small portion of these water powers have been developed, even with the stations now operating and the transmission systems now carrying power throughout the central portion of the State, the conditions would seem to make profitable the operation of at least some of the railroads by electricity. It was stated that the capacity of the steam locomotive has to be that of the maximum effort required from it, even though that effort be for a very short time, while, on the other hand, the load on the power station is only the sum of the loads on the different motors, which will average much less than the sum of their maximum powers. This materially reduces the cost of operating, especially with the conditions found on the Pacific coast, where several power plants can feed into one network and supplement the power of each other.

Dewhurst Slag Ladle and Car; Side Tipping; Double Truck.

Dewhurst Slag Ladle and Car; Side Tipping; Single Truck.

Dewhurst Slag Ladle and Car; End Tipping.

or tipping poles required. It will be noted that the chain and tipping mechanism for side-tipping ladles can be placed on whichever side of the car the dumping is to be done. The chain runs over steel snatch blocks and guide pulleys, the latter and two of the snatch blocks being attached to the car, and the other snatch block being attached to the ladle as shown. The chain is provided with hooks at each

Railway Club on the 21st ult., in San Francisco, Cal. The paper was presented by Robt. McF. Doble, consulting engineer of the Abner Doble Co. of San Francisco, and was illustrated with views and diagrams of steam locomotives, electric cars and locomotives, track and rolling stock of California roads, hydro-electric plants, and a State map showing the location of power plants and transmission lines. Attention

The possibility of recovering energy lost in braking was also referred to, the example of several European railways being cited to emphasize the fact that this has been practically accomplished. In such a system of distribution as is possible in California, considerable power might be generated by trains descending mountain divisions and this fed back and utilized. Under the third heading reference was made to the

saving in the cost and maintenance of track, the possible increase in capacity of existing railroads, the saving of time and labor in the operation of an electric locomotive, its characteristic simplicity and the rapidity with which repairs can be made. The power which can be obtained from steam locomotives is rapidly approaching its limit, while the development of the electric locomotive has apparently only begun. The relative reliability of the steam and electric was held to be in favor of the latter, especially in consideration of the local conditions in California, where a number of water-power plants feeding into the same distribution system would make exceedingly remote the possibility of breakdown of anything more than an individual locomotive, and the chances for that were only half those for the steam locomotive.

For comparison, Mr. Doble next considered briefly some of the typical modern steam locomotives, such as those of the Southern Pacific Company, the 4 cylinder balanced compound 3000 type of the New York Central, and the large Hallet articulated compound built for the Baltimore & Ohio Railroad.

After some general observations on the development of electric traction, with special reference to its growth in California, the author took up the discussion of several different types of electric locomotives using direct current, particular mention being made of those built for the Baltimore & Ohio and the New York Central Railroads. The "6000" New York Central electric locomotive was described in detail, attention being called to its interesting electrical features and to its remarkable power and speed qualities as developed in the recent tests. Comparisons were also made between the electric and the heaviest Atlantic type steam locomotive of the New York Central, with particular reference to the increased draw-bar pull per pound of weight of the former.

The advantages of the multiple unit direct current system were next treated, mention being made of some of the typical installations in the Eastern States, as well as the Key Route and North Shore Railroads near San Francisco.

Under alternating current polyphase systems, Mr. Doble discussed the progress which had been made along that line in Europe, and described the Valtellina, Jungfrau and Burgdorf-Thun systems. Mention was also made of the remarkable Berlin-Zossen high-speed trials.

Single-phase systems were next taken up, attention being called to the pioneer work of B. J. Arnold, the General Electric and Westinghouse systems and their special features, and the system designed by J. H. Hallberg.

Turning to the achievements of electric traction in California, particular reference was made to the Los Angeles & Redondo Railway, the Pacific Electric Railway of Los Angeles, and the North Shore and Key Route systems of San Francisco. The North Shore Railroad is of special interest by reason of its being the first and only third-rail line in California, and because of its being operated from a sub-station which is the terminus of one of the longest transmission lines in the country. The Alto station referred to is 180 miles from the hydro-electric plant at Colgate, and 250 miles from the new De Sabla power house. One of the features of the Key Route system, which was given considerable attention, was the Diamond trolley, which is successfully used on all of its trains. The possibilities of this collector for heavy railroad work were pointed out.

As to projected electric lines on the Pacific coast, reference was made to improvements which the Southern Pacific Company has under consideration for its suburban lines in Oakland, Berkeley and Alameda, to the rumored electrification of that company's San Jose and Port Costa lines, and also to the possibility of operating its mountainous divisions by electricity. Mr. Doble concluded with some interesting remarks on the leading hydro-electric power stations and transmission systems of California. The distinguishing characteristics of each plant were mentioned, and special reference was made to the new De Sabla power house of the California Gas & Electric Corporation, where is now operating an 8000 H. P. tangential water wheel, stated to be the largest single water wheel ever constructed. This station regularly supplies power to San Francisco and other points 300 miles distant.

### The Simplon Tunnel.

The Simplon tunnel, driven through the Swiss Alps, met with many obstacles during construction. It is 12½ miles long, and is the longest tunnel in the world. Its altitude above sea level (2310 feet) is much lower than that of any other Alpine tunnel, which accounts for its great length. The Arlberg is 6½ miles long and 4300 feet above sea level. Work was started in August, 1898, simultaneously from the Swiss and Italian sides. All the workmen (10,000) are Italians, 4000 beginning work at Brig, Switzerland, and 6000 at Iselle on the Italian side. It was believed that the rocks were composed of vertical strata, but they proved to be horizontal on the Italian side. Great streams of water were met, which required much energy and skill to turn aside. After this difficulty had been overcome the engineers came upon a bed of moving sand. Heavy timbers were used to stem its rush, but they went to pieces

under the enormous pressure and were replaced by steel stays to hold up the metal plates to keep out the sand. Last but not least, hot springs were encountered around which they had to work.

The rock through which the tunnel is being driven is mostly granite. By means of machine drills the Swiss side was advanced 20 feet daily, and often more, an unprecedented result. The drill used is 3 inches in diameter, rotates slowly and is kept at its work by a hydraulic pressure of 1500 pounds to the square inch or ten tons on the cutting face of the drill. The water encountered is discharged along the axis of the tool, and in this way it is kept cool and the rock cut away is washed out. The entire undertaking consists of two parallel single tunnels 56 feet apart, which are connected at every 300 feet by transverse galleries. By means of these galleries one tunnel will ventilate the other.

The workers in the tunnel are supplied with 58,000 cubic feet of air per minute, spray and ice arrangements being introduced for cooling the air. The water discharged from the north and south ends of the tunnel by means of drains is 5000 gallons per minute. Shifts were changed every eight hours. The men are brought out in heated cars and taken to a warm station, where they change their clothes. Ample provision for hot and cold douche baths was made. The workmen's clothing was hung up in hot rooms to dry, in order that it might be in a fit condition for the next day's work. A restaurant was connected with the station, where food of excellent quality was served at a small price. Sleeping apartments were also arranged for the men at a very low price.

The tunnel cost nearly \$20,000,000. When the hot springs were met it was an impossibility for men to continue at work beyond thirty minutes at one time on account of the excessive heat created by the hot springs, with a temperature of 46° C. (115° Fahr.) in the first gallery.

## Gold Mining in Rhodesia.

### NUMBER IV.

Written for the MINING AND SCIENTIFIC PRESS by F. C. ROBERTS.

Continuing the consideration of mining costs, the several factors have been treated separately, the cost per ton being based upon a tonnage of 44,011 tons. The most important of these are mine pumping, winding, underground tramming, rock drills and their sharpening, etc.

#### MINE PUMPING.

	Total Cost.	Cost Per Ton.	Total Cost, %.

**MILLING.**—The introduction of heavy stamps, with an object of obtaining a large stamp duty, seems to have reached its practical limits, i. e., 1465 pounds. In Africa the mill is operated more as a crushing machine, than with an idea of effecting perfect amalgamation, and so long as the ores being dealt with lend themselves readily to subsequent treatment by cyanide, in the state of fineness produced through using a low discharge, and a coarse screen (20 to 25 mesh), a high duty may be expected to be retained. The popular method of operating the stamp mill, that is to say, the number and order of drops, is as follows:

Order of drop..... 1, 3, 5, 2, 4  
Height of drop..... 8 inches  
Number of drops per minute..... 4.96

As a further means of increasing the stamp duty, double crushing with rock breakers is resorted to, when the product being fed to the mill is, in the first case, crushed to about a 2½-inch ring and then passed over grizzlies, the coarse being fed to No. 2 crusher, when it is reduced to about a 1-inch ring.

This method of relieving the stamps might, in the opinion of the writer, be economically extended to a No. 3 crusher.

That most important branch of mining, "sorting," is almost entirely neglected in Rhodesian practice, and many tons of rock are sent through the mill, which is not high enough in grade to compensate for the wear and tear for which it is responsible.

Extending over a period of twelve months, with rock breaker capacity sufficient to reduce the product to a 2 inch ring before entering the mill, the writer has obtained a duty, with 1265-pound stamps (an effective duty of 1150 pounds), of 5.5 tons per stamp per day, using a 2½-inch discharge, 20 mesh screen, 7 tons of water per ton of ore, and the mill running at ninety-six 8 inch drops per minute.

It is a well-known fact that the stamp mill, under ordinary conditions of use, performs a large amount of unnecessary work, that is to say, the product, when it has been reduced to the fineness indicated by the screen being used, is not immediately discharged, hence the ore is reduced to a much finer state of division than there is, from a crushing point of view, any necessity for.

In recent years a great deal of attention has been given to this subject, with the result that there is at present several subsidiary crushers on the market, for which various results are claimed, when used in connection with the stamp mill. As an illustration of the product furnished from the stamp mill, it may be stated that the writer has found through sizing the product produced when using a 10-mesh screen, and the other operating conditions being similar to those noted above, that 82% of the discharged product will pass through a 30-mesh screen, and by further sizing, recrushing the oversize to a uniform fineness to pass a 30-mesh screen, it is possible to obtain a duty of nearly 9.5 tons per stamp per day.

In this case a 30-mesh screen was used because it was possible to obtain a maximum extraction when the ore was reduced to this fineness. Other experiments carried out upon the same lues gave equally satisfactory results, although the increased duty is, of course, proportional to the state of fineness desired.

The writer is at present making some further tests upon a working scale, which should furnish some interesting results.

(TO BE CONTINUED.)

As SCIENTIFIC investigation proceeds, it is found that some of the more rare minerals possess remarkable and valuable properties when associated artificially with some of the most abundant of the world's minerals. Iron is one of the most abundant and most widely distributed of minerals. Molybdenum in its

several forms is of comparatively rare occurrence. Nickel, also, is far from common. Tungsten is seen so seldom as to be wholly unknown to most of those whose business is mining, and yet the association of either of the above mentioned rare metals with steel produces marvellous effects, toughening and hardening the steel to a greater extent than has ever been found possible without them; and yet this branch of metallurgy is practically in its infancy. The number of substances known to us as elements have increased by the discovery of new elements from time to time, and without doubt the intelligent investigations constantly in progress will result in the discovery of still other unresolvable substances. Twenty-five years ago sixty-four elementary substances were known. The list to-day comprises at least seventy-five, with the possible addition of one or two more—radium being one of them. It is not claimed by chemists that all of the known elements of to-day are simple substances, unresolvable into more than a single substance, for further research may discover this to be untrue.

### Coolgardie, Australia, Pumping System.

The Coolgardie goldfields, which is a common name for the great groups of mines at Kalgoorlie and Coolgardie and the immediate neighborhood, lie 363 miles

sumption, was worth 2s 6d per gallon, and scarce at that. The Government excavated tanks and built dams on the roads to the fields. As the mines developed, at the lower levels salt water was found, which was distilled and sold at 70s per 1000 gallons. In this way some sort of a provision was made, but the water supply was still a danger point in connection with the fields. Typhoid fever raged. Owing to the extreme saltiness of the water (there being 30 ounces of saline matter to the gallon), a quantity of fine gold was lost.

In 1894 the railway had been extended to the Goldfields, i. e., Coolgardie and Kalgoorlie. The difficulties of working the traffic were enormously increased owing to the trouble of obtaining fresh water at almost any price. For example, the cost of water alone to the railway department was £1000 per day during the summer. Such a state of affairs could not last, as it meant an immense increase in the cost of living on the fields. As gold was being found at other places, such as Menzies, Leonora, etc., the railway would of necessity have to be extended, and water, therefore, was indispensable. Various schemes were propounded, and several offers were made to the Government by groups of capitalists to build and work water works to supply the fields if a concession was granted them. An attempt was made to obtain water by boring, but after going down 3000 feet through granite the attempt was given up.

tions were carried down nearly 100 feet below the level of the river. At the base of the foundations the thickness of the dam varies from 85 to 120 feet, tapering to a width of 15 feet on the top; 69,000 cubic yards of concrete were used in the construction. The surplus water flows over the crest of the dam. The reservoir or lake thus formed is 8 miles long and contains, when full, 4,600,000,000 gallons of water. The catchment area consists of 850,000 acres, and consists chiefly of granite hills. The water is exceptionally good. At a trifling cost it would be possible to divert other streams into the reservoir, and so largely increase its capacity. Suitable valve towers are provided to regulate the flow to the first pumping station.

A patent locking bar pipe was used. This pipe consists of two steel plates rolled into semi-circular form, the edges being upset and a locking bar forced on. The joint is then finally clamped or closed by hydraulic machinery. The diameter of the Coolgardie pumping mains is 30 inches, each pipe being about 28 feet in length, made of plates  $\frac{1}{8}$ -inch thick, and weighing about 1½ tons. In some sections, where extra pressure existed, the pipes were made of plates  $\frac{1}{4}$ -inch thick. The total number of pipes required was about 60,000 for the main to Coolgardie, and the total estimated weight of steel plate was about 76,000 tons. Each pipe was subjected to a hydraulic pressure test of 400 pounds to the square inch, was then

Scenes Along the Kalgoorlie, Western Australia, Pipe Line.

in a direct line from the port of Fremantle, on the west coast of Australia. The first 100 miles crosses a series of granite ranges averaging 1200 feet high, covered with gum trees, etc. The country then becomes a series of broken rolling plains, gradually rising toward Coolgardie. The soil, with the exception of a few patches, is sandy and covered with scrub gum trees, etc. The average rainfall is 7.14 inches, evaporation 82.6 inches, with a temperature often over 100° F., there being in the old days only a few soaks and native wells available for the supply of water.

In 1892 the first discovery of gold in paying quantities was made near the site of the present town of Coolgardie. Until the discovery of gold, this desolate and waterless country had been crossed several times by explorers. When the great rush of 1893 set in, the want of water caused suffering and loss of life, largely due to typhoid, and as the railway only ran to Southern Cross, 25 miles from the coast, the remainder of the distance had to be done in stage coaches or other vehicle. As the gold area increased and the gold-bearing reefs and formations showed signs of permanence, the Government did all possible to minimize the suffering and loss due to the shortness of water. Inferior water, hardly fit for human con-

C. Y. O'Connor was instructed to inquire into the cost and best method of carrying out a scheme for the supply of water from the coastal or well-watered districts. In July, 1896, he reported in favor of a scheme which consisted of a reservoir to be built on the Helena river, near Mundaring, in the Darling ranges, 20 miles from Perth, the water to be then pumped through a main to Coolgardie. In the first place 1,000,000 gallons was estimated as the probable requirement. This quantity was, however, increased to 5,600,000 gallons per twenty-four hours, and the estimated cost was set down at £2,500,000, exclusive of the reticulation of the towns en route. In September, 1896, was introduced the necessary bill, which met with opposition but was ultimately passed. In September, 1898, the Goldfields construction bill was passed by the Legislative Assembly. The main supply reservoir is situated in the Darling ranges, 30 miles from Perth, 320 feet above sea level, where two great arms of granite jut out across the narrow valley, at the bottom of which flows the Helena river. A gigantic dam of concrete is placed like a huge wedge between these two granite arms, thus closing up one end of the valley. It is 760 feet long and 100 feet high in the deepest part, and the founda-

immersed in a bath of hot asphalt and kept there until the steel rose to the same temperature as the bath itself, this coating to act as a preservative against rust. The circumferential joint consisted of a forged steel sleeve with a lead caulked joint. The pipe was laid partly in a trench and then covered to a uniform thickness of 2 feet with soil, except where it ran through salt country, where, to avoid corrosion, the pipe was laid on trestles and protected from the sun by suitable coverings. No expansion joints were used or found necessary. The lead joints of the circumferential steel sleeves were made by a specially designed caulking machine, this machine being driven electrically for a considerable portion of the time, but latterly the electrical drive had to be abandoned, owing to difficulty in getting water for the engine, and the machine was worked by hand. The lead joint where the locking bar comes in was caulked up by means of a small hydraulic press. An average of from twenty to thirty joints per working day of eight hours was accomplished by the machines. The pipe contracts were signed October 24, 1898, by two Australian firms, Mephan-Ferguson and Hosking Bros., who erected special works at Midland Junction and Falkirk, West Australia. The total contract price

for the pipes delivered to works in West Australia amounted to £1 025,000.

As the Coolgardie water supply scheme had to depend absolutely on mechanical means for forcing water through, the question as to the type of machine and boiler had to be gone into carefully, as the entire success of the scheme depended on the working of the pumping machinery. The problem was to pump 5,600,000 gallons for twenty-four hours against a total estimated head, including friction, of 2,700 feet, through a pipe 30 inches in diameter, and roughly, 330 miles, the speed of the water through the pipe being taken at about 2 feet per second.

From stations 1 to 4 in each station there are three complete sets of pumping machinery and boilers, any one of which is capable of pumping 2,800,000 gallons per twenty-four hours against a head of 450 feet, so that, to get the full quantity of water, two sets of engines and pumps are always pumping together into the main, and one set is "spare." From stations 5 to 8, inclusive, there are at each station two sets of

elevation of 1457 feet. Each station is provided with concrete tanks of 1,000,000 gallons capacity, which acts as combined receiving and suction tanks. From Dedari the water is pumped a distance of 12 miles to the main service reservoir at Bulla Bulling. This reservoir is of concrete reinforced with barbed wire strands, and holds 12,000,000 gallons. Bulla Bulling supplies a small service reservoir of 1,000,000 gallons on Toorak hill, overlooking the town of Coolgardie, the mean elevation being 1525 feet. The total head pumped against in daily working at stations Nos. 1 to 4 varies from 360 feet to 410 feet, depending on whether one or two engines are working. At stations Nos. 5 to 8 the head is from 180 to 210 feet. From Toorak tank the water runs by gravity to a reservoir on Mount Charlotte, which is to supply the town of Kalgoorlie.

In October, 1899, tenders for the machinery were called for by the Government, which, acting on the advice of its engineer experts in London and Australia, decided to accept the tender of Messrs. James

calorific value of 10,000 British thermal units per pound. The Government engineer for the Coolgardie water supply selected a group of machinery at the No. 2 pumping station, and at the No. 8 pumping stations for the purposes of running the official trials. At the No. 2 pumping station the trial resulted in a duty of 142,093,598 foot pounds of work being obtained per 1,000,000 British thermal units, showing margin of 7,093,598 foot pounds of work in favor of the engines. The working duty trial resulted in a duty of 144,427,000 foot pounds of work being obtained for each 160 pounds of coal consumed, showing a margin of 9,427,000 foot pounds in favor of the engines. The amount of water pumped during the twelve hours by the two groups of machinery was 2,998,081 gallons. At the No. 8 pumping station the trial resulted in a duty of 142,934,958 foot pounds of work being obtained per 1,000,000 British thermal units, showing a margin of 7,934,958 foot pounds of work in favor of the engines. The working duty trial resulted in a duty of 148,141,000 foot pounds of work being obtained for each 160 pounds of coal consumed, showing a margin of 13,141,000 foot pounds in favor of the engines. The quantity of water pumped by the engines during the twelve hours was 3,147,559 gallons, showing an excess of 347,559 gallons.

The fuel to be used is a local coal obtained from the Collie coal fields of Western Australia. It is estimated that 30,000 tons of coal per annum will be required when the plant is running full time—twenty-four hours. The Government has therefore put in railway sidings at each pumping station and has erected coal bunkers under cover capable of holding some 200 tons each. The trucks of coal are run onto an elevated timber gantry and the coal then unloaded.

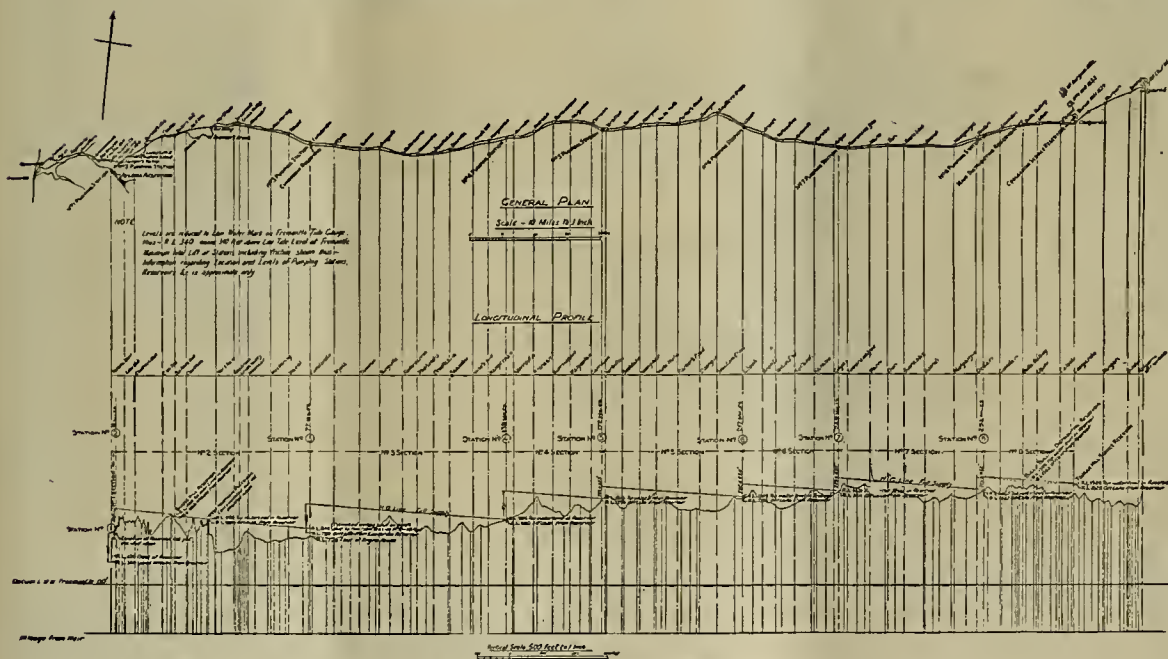

A great problem was to get the plant, which weighs 3500 tons, out to the colony, and when there to get each piece of machinery sorted and sent on to its proper station and erected—twenty groups, each consisting of an engine and boiler, distributed over 330 miles of country. An ingenious system of shipping was adopted. Each group was given a distinctive color and letter, and every part of the group was painted with the distinctive color to which it belonged. When the parts were cased one end of the packing case was also painted with the correct group color. In addition, each case or package was numbered consecutively and marked with the group letter. All marks were in duplicate, one set being painted on the case or package and the other stamped on sheet tin tabs which were fastened on to the cases or packages. No parts of the different groups were allowed to be packed in the same case. By these precautions all trouble was avoided. The railway, shipping and wharf men were supplied with colored group key plans, and so were able to pick out at once the various cases and packages belonging to each group and send them on to their correct destination. There were 5000 packages, and the only complaint received from the erection staff as to missing material referred to one ½-inch hydraulic valve.

In most countries where water works or other engines are to be erected the site of the engine house, etc., is situated within reasonable distance of some town or available place, where men could find lodging and food, and where supplies, stores, etc., could be obtained. On the Coolgardie contract this was not possible. Most of the engine sites are miles away from any source of supply, not only of food, but of what is in a dry country even more necessary—water. The time given for the completion of the work, viz., twenty-seven calendar months, was exceedingly short, bearing in mind its magnitude. It was, therefore, necessary to arrange for the engine and boiler erection to be carried on simultaneously at the eight stations. The arrangements were made as follows: Sufficient land was leased from the Government by the contractors, James Simpson & Co., Ltd.

This plot of land was enclosed and on it was erected the permanent camps, workshops and mess rooms. The object in having the land formally leased was to enable the contractors to insist that every one who came within the enclosure and enjoyed the use of the camp should conform to the regulations laid down for its running. The most stringent regulations as to sanitation were rigidly enforced, with the result that no serious case of illness in any of the camps occurred. In addition to the camps for the men to live in, small workshops were erected, both for the storage of tools, gear, machinery, and the carrying out of small repairs. At No. 3 station the general workshop and store was erected. The plant was driven by a suitable engine and boiler, and the largest lathe could handle the outside piston rods, some 17 feet long, or turn up a low pressure piston. In a country where labor is dear it paid to have the best mechanical appliances that could be bought. The plant was erected with care and has given results of value on the work.

Such, in abbreviated form, is the history of the

### MEPHAN-FERGUSON'S PATENT RIVETLESS OR LOCKING BAR STEEL PIPE.

Profile Along the Kalgoorlie Pipe Line.

machinery, each set of machinery being capable of pumping 5,600,000 gallons per twenty-four hours against a head of 225 feet, so that while one set is pumping the other set is "spare." Station No. 1 is close to the foot of the great dam on the Helena river. The water is elevated 421 feet in daily work into an open concrete tank of a capacity of 468,000 gallons, situated at No. 2 station, the total distance from No. 1 being about 1½ miles. From station No. 2 the water is pumped up about 360 feet through 23 miles of main to the first regulating tank at Baker's hill, about 1080 feet above sea level. This tank is of concrete, with a capacity of 500,000 gallons. The water runs from Baker's hill by gravity to a second regulating 500,000 gallon concrete tank at Northam, 18 miles farther on, the Northam tank being 94 feet lower than Baker's hill. Still falling, the water reaches the great tank at Cunderin, which holds 10,000,000 gallons, and is 78 miles from the Helena reservoir. Stations 3 to 7 pump the water against a steady rise to the eighth station at Dedari, a distance of 217 miles from Cunderin, and situated at an

Simpson & Co., Ltd., of London, a special clause being inserted in the contract giving them permission to have half of the manufacturing done by the Worthington Company. The contract with the West Australian Government provided that each of the pumping engines should attain throughout a twelve-hour trial a duty of 135,000,000 foot pounds of effective work per 1,000,000 British thermal units supplied to the engine, which would not be returned to the boiler in the ordinary course of working. It also provided that, for the purpose of testing the combined working duty of the pumping engines and boilers, two groups of machinery at one of the first four stations and one group of machinery at one of the second four stations should be capable of pumping through the main to the next reservoir not less than 2,800,000 imperial gallons of water during a twelve-hour trial; and that the combined duty of the group should throughout such a trial amount to at least 135,000,000 foot pounds of effective work for every 160 pounds of coal consumed, such coal being equal to a fair sample of good Collie (W. A.) coal, having a

greatest pumping scheme that has ever been carried out. The whole scheme was started and the water pumped through to Kalgoorlie without a single accident. The scheme has now been working for over two years without accident.

## Mining and Metallurgical Patents.

PATENTS ISSUED FEBRUARY 14, 1905.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

EXCAVATING MACHINE.—No. 781,738; N. D. Petrie, Celina, Ohio.

In excavating machine, turntable supporting dredging mechanism, pair of cylinders, connection between piston rods of cylinders and turntable, means for supplying water under pressure to either cylinders to exclusion of other thus to effect rotation of turntable, and means actuated by driven piston to effect automatic shutting off of water to that cylinder.

PROCESS OF TREATING PRECIOUS METAL-BEARING ORES.—No. 781,711; A. H. Brown, Boulder, Colo.

Process for treatment of ore consisting in pulverizing ore in presence of cyanide solution, subjecting ore to hydraulic classification by introduction of cyanide solution at bottom of overflow tank to produce ascending current; leaching ore by use of cyanide solution whereby finer values of ore are dissolved; removing dissolved metallic values from ore in any suitable manner; and subjecting residue of ore to concentration.

PROCESS OF SMELTING NATIVE COPPER-BEARING ROCK.—No. 781,807; F. R. Carpenter, Denver, Colo.

Process of smelting native copper-bearing rock which consists in adding thereto basic material, to form slag and sulphide material to form matte or carrier for native copper and incidentally gold and silver that may be present and smelting mixture.

BARREL FILTER.—No. 782,031; H. C. Holthoff, Milwaukee, Wis.

In barrel filter combination with rotary barrel of approximately cylindrical filter frame arranged axially within barrel and composed of sectional inner and outer shells having coinciding cells and perforations in inner and outer walls of cells, and suitable filter body interposed between shells.

STAMP MILL.—No. 781,912; R. Schorr, San Francisco, Cal.

In stamp mill for crushing ore, mortar, with outwardly flaring sides, die in bottom thereof, dropping stamp therein, means for supplying water thereto, screens at top of mortar extending inwardly from top of flaring edge, and means for conveying away water and suspended material passed through screens by action of stamp.

FURNACE.—No. 782,438; Louis De Rome, San Francisco, Cal.

Furnace consisting of inclined hearth with escape flue rising from near head thereof, roof overhanging hearth, reservoir adapted to contain crucible below lower end of hearth, draw-off spout from bottom of reservoir, furnace front having burners projecting therethrough, one discharging within reservoir and other directed upon hearth, closed opening through roof coincident with reservoir, depending lip from roof at angle of flue, and a projection of rear wall overhanging head of hearth.

AMALGAMATOR.—No. 782,611; M. V. Lasswell, Oakland, Cal.

In fine gold amalgamator, plurality of containers communicating with each other and provided with openings in bottoms, sluice box communicating with initial container, yoke-shaped bearings secured to sluice box, shaft rotatably and removably journaled in bearings and provided with grate bars depending across sluice box, pipe having one end communicating with receptacle and its other end open, removable plug mounted in open end, couplings connected to pipe and bottoms of containers and through which openings communicate with pipe, valve plugs rotatably mounted within openings, and operating rods each having one of ends connected to one of plugs and other end extending upwardly through cover of container.

PROCESS OF INDUCING A FLOW OF OIL FROM OIL WELLS.—No. 782,233; B. F. Gardner, Chicago, Ill.

Process of inducing flow of oil from oil well by vaporizing oil or converting water into steam at bottom of well by application of heat to produce sufficient pressure to cause oil to flow up from bottom of well.

EQUALIZING MECHANISM FOR AIR COMPRESSORS.—No. 782,597; E. Cheshire, Milwaukee, Wis.

In two-cylinder air compressor, combination with two cylinders, their pistons, and means for concurrently moving pistons in opposite directions, of a port connecting clearance spaces in cylinders, valve in port, and means for moving valve so as to temporarily open it just as each piston is about to terminate its compression stroke.

## MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

### ALASKA.

The December, 1904, report for the mines at Treadwell, Douglas Island, shows that the Alaska-Mexican 120-stamp mill ran 294 days; crushed 18,307 tons of ore; estimated realizable value, \$25,571; saved 312 tons sulphurets; estimated realizable value, \$22,014; working expenses, \$32,159. The Ready Bullion 120-stamp mill of the Alaska United ran 291 days; crushed 18,730 tons ore; estimated realizable value, \$24,138; saved 320 tons sulphurets; estimated realizable value, \$28,111; working expenses, \$31,206. The Alaska Treadwell 240-stamp mill ran 291 days; 300-stamp mill ran 27 days; crushed 78,256 tons ore; estimated realizable value, \$76,664; saved 1737 tons sulphurets; estimated realizable value, \$73,992; working expenses.

### ARIZONA.

#### Cochise County.

(Special Correspondence).—The work of changing the shaft timbers and placing in the guides for a cage at the Silver Thread, one of the properties of the Tombstone Con. Co., at Tombstone, has been completed and hoisting has commenced. The ore body recently uncovered on the 600-foot level is one of the largest discovered in that property for some time and was found below the old water level, showing that the mines of this district continue to go down. The ore is of high-grade silver containing considerable lead and good values in gold. At the big shaft of the company the work of exploration on the 800-foot level is under way. The pumping record averages 3,500,000 gallons a day and the shipments of ore continue the same.

Tombstone, Feb. 21.

#### Gila County.

(Special Correspondence).—The Old Dominion's smelting cost at its new plant, at Globe, is \$3.50 per ton as compared with between \$5 and \$6 at its old plant. Its mining cost, including extraordinary development work and expenses of its new shaft, is \$4.50 per ton as compared between \$6 and \$7 per ton. This reduction in costs with the high price for the metal permits of the treatment of 5% ore.

Globe, Feb. 20.

#### Martocopa County.

(Special Correspondence).—D. Cleberat is developing claims on the Hassayampa near Morristown. G. Hamlin reports the mill at the Relief mine closed down because of scarcity of fuel. The recent rains have made some of the desert roads almost impassable. E. H. Winters is working a gold property near Winters.

Phoenix, Feb. 20.

#### Mohave County.

(Special Correspondence).—There are twenty men on road work and in the mines of the German-American Co., near Vivian. This company is to put in a milling plant. The main shafts on two mines of the group are now down 200 feet and sinking is still being continued. Above these levels the mines have been thoroughly developed, showing bodies of milling ore.

Vivian, Feb. 19.

The Golden Gem M. Co. will build a mill on their property, near Cerbat, if sufficient water can be developed, otherwise they will build at Kingman or McConico. B. F. Hall represents the company. The Tub mine in Union basin, near Cerbat, is being developed by B. F. Hall. T. R. Garner, general manager of the St. Louis mine at Cerbat, will let a contract for 500 feet of drifting.

#### Santa Cruz County.

Near Jefferson Camp, C. O'Keefe and G. Wieland will resume work upon the Redmen mine. They have a tunnel in 100 feet on a copper ledge 4 feet wide and a 30-foot shaft below the tunnel level. G. Wieland is developing the Red Rock and Blue Rock.

#### Yavapai County.

(Special Correspondence).—The Anderson Metals Extraction Co. has commenced work on the foundations for eleven cement tanks at McCabe for its cyanide plant to work the tailings under royalty produced by the Model G. M. Co.'s mill. These tanks will be 43 feet in diameter and 4 feet high. There are 25,000 tons of these tailings. The company expects its machinery to arrive within the next sixty days from the East and hopes to be operating by May 15, running 100 tons a day. They have ten men at work on the plant.

McCabe, Feb. 20.

(Special Correspondence).—At the P'au mine, 8 miles south of Jerome, forty men are working and the mill construction will be completed by March 1. The ore is crushed by friction in a tube mill. A large cylinder is revolved horizontally and when partly filled with ore the rotation thereof grinds the mass into the finest kind of particles that can easily be plated and then cyanided.

Jerome, Feb. 21.

(Special Correspondence).—The Oro mine, near Minnehaha, has closed down because of lack of water, as for some time there has been hardly enough water at the Oro property to run ten tons of ore a day through the mill, which has a capacity of 150 tons. The main shaft of the Oro mine is down 555 feet and will be sunk deeper to develop water enough to operate the mill.

Minnehaha, Feb. 20.

### CALIFORNIA.

#### Butte County.

W. P. Hammon has returned from the East, where he arranged for the construction of seven more dredgers to operate in the Yuba river gold field, where the syndicate has two machines working and four under construction in the Yuba river tract. In addition the Marys-

ville Gold Dredging Co., John Martin's concern, has contracted for two dredgers of the same style. Each machine costs about \$90,000. While extracting the gold for the owners the tailings from the river bed are being thrown up to construct an immense barrier for the government across the channel of the Feather river. When they complete the contract the dredgers will continue mining operations behind the barrier, the latter being protected while it prevents a flow of debris down the river. The barrier is part of the great works planned by the government to prevent quantities of sand and gravel from flowing down Feather and Sacramento rivers, and when plans for it were made, dredger mining in the river was commenced. The government saves many dollars by this mode of construction. These dredgers are the largest in the world, being built to work gravel 60 feet below the surface or twice the depth worked elsewhere. The Hammon syndicate will also construct more dredgers at Oroville, two being contracted for recently.

#### Calaveras County.

It is reported that a 7-foot ore body has been struck at the Gwin mine. D. McClure is superintendent. The Hagerman gravel mine on the Calaveras river, near San Andreas, is being opened by D. P. Gray. D. A. Nunes, superintendent of the Nunes mine, near San Andreas, is running a bedrock tunnel to tap the gravel channel. A mill may be put up when the channel is struck. D. Fricot has bought a large whim for the Johnson mine at Canada hill. J. B. Luddy is superintendent.

At the Essex Con. mines, near Angels, the shaft is being unwatered and put in shape for reopening the lower levels. The 150-foot level in the shaft is being retimbered preparatory to development and stoping there, and the 250-foot level is being explored, and drills will be breaking ore there in a few days. The Allison tunnel has been explored by hand drills along the vein for 120 feet and found to warrant an air pipe line 4000 feet long, when power drills will be put to work at once. This pipe line, also passing through the Harrison tunnel portal, will be there tapped to supply drills there, when the present face will be extended across the formation about 50 feet to cut another vein west, which crops strongly on the surface. A tramway 1000 feet long has been surveyed and will be put in from the mine to the railway track, where a spur has been built. The 40-stamp mill is being overhauled and will start up in a few days. J. Meyers is manager, F. R. Crocker superintendent and E. C. Wood engineer.

#### El Dorado County.

The Witmer and Fuller mines, near Placerville, are being worked by T. Clark, superintendent of the River Hill mine. An air compressor will be put on the property, and the ground is being cleared for a hoist. At Greenwood the Oliver mine is down 300 feet and sinking with three shifts. The Santa Claus and Short Handle mines are being unwatered. A new pump has been put in the 90-foot shaft of the Cora Dora, near Grizzly Flat. Sinking has been started at the Bacon mine at Gold Hill.

#### Nevada County.

Superintendent A. D. Foote of the North Star mine, near Grass Valley, has added three tanks to the electric precipitation cyanide plant and is building others.

R. D. Jackson and D. R. Finlayson are building a 50-ton cyanide plant to treat the tailings from the Empire mine near Grass Valley.

#### Placer County.

The old Dardanelles tunnel is being worked by J. H. Myers and A. G. Read of Forest Hill. This mine was formerly worked by hydraulicking, and then, on the channel going into the divide, drift mining was started, until at a distance of 2400 feet a deep cross channel was found cutting through the main channel, but excessive water finally caused its abandonment. The present owners are continuing the old tunnel from the worked out channel on and through the cross channel. It is estimated that when in 800 feet the tunnel will encounter the continuation of the "white lead." The Paragon mine at Bath is being worked by W. Rhea of Forest Hill. At Last Chance, near Forest Hill, J. H. Myers and B. E. Caples are working the Bay State, and D. M. Ray has charge of the El Dorado Co.'s property. The Tadpole mine at Canada Hill will erect a mill with a capacity of sixty tons per day.

#### Shasta County.

A 4-stamp triple-discharge quartz mill has been put in on the Crown Point mines on Mule mountain, west of Redding, by G. P. W. Jenkins and operations at the mine have been resumed. The Crown Point is 1 mile from Larkin and 2 miles east of Clear creek. Electric power will be used to run the mill, the current being secured from the Northern California Power Co.'s line running to the Heintz dredger.

#### Siskiyou County.

Ladd & Patton, operating in the Big Bend district on South Fork, near Cecilville, are preparing to put in a small mill on their quartz property. The Salmon River M. Co. are working the Conzett hydraulic claim, near Cecilville, with two 6-inch giants. L. Monahan is superintendent of the Gold Dyke mine, near Cecilville, and is crushing good ore in the new Huntington mill. W. H. Young, superintendent of the King Solomon mine, will put a cyanide and milling plant on the mine as soon as a road can be built to Black Bear.

#### Trinity County.

At the Fairview mine, near Minersville, thirty stamps are dropping night and day on good ore. The quartz mill is run by water, the power being furnished by the company's new ditch from Stuart's Fork. The mine is equipped with an up-to-date electric plant which furnishes power for the saw mill, lighting and other mine purposes. A force is running a lower tunnel, which, when completed, will give 400 feet of backs. It is now in 600 feet. There are 135 men on the company's payroll. J. A. Brent, manager of the Quimby gold mine on Quimby creek, near Blue lake, will put a large force at

work, building the 9-stamp mill and work the property on a large scale.

#### Tuolumne County.

A gallows frame is being built at the Hard Times mine, near Arrastraville, and it is expected that the mine will soon be producing ore. The Star mine and mill, near Columbia, are running steadily with twenty-two men. The Clio mill at Jacksonville is being overhauled preparatory to starting up. The shaft of the Longfellow mine at Big Oak Flat has been sunk over 600 feet.

### COLORADO.

(Special Correspondence).—The Bureau of Mines in the State house at Denver opened the exhibit of minerals that was on display at the St. Louis Exposition. The independent oil producers of the State are organizing to secure legislation in favor of the independent companies and curbing the trust. An independent refinery is being talked of by the State. A bill is now before the Legislature proposing the building of a State refinery. It is understood the United Oil Co., an auxiliary of the Standard Oil trust, has recently cut the price of oil in this State, and the independents will try and improve conditions now existing throughout the State. The Federal Court at St. Louis has decided against the Venture Corporation of London in their suit against the Stratton estate for \$6,000,000 damages, claiming that the mine had been "salted."

Denver, Feb. 20.

#### Clear Creek County.

(Special Correspondence).—The mining industry in lower Clear Creek county shows an improvement over one year ago. The Independent Smelter, at Golden, has purchased the Kilton Sampling Works and made some improvements. They have added a new crusher and Vezin sampler. Since the starting of the smelter at Golden it is understood the trust has reduced the treatment charges on ore from this district to \$3. The Independent Co. say they will not meet the rate, but will only take such ore as they are able to make a profit on. It is understood the larger companies in the district have contracts with the trust and that most of the business now secured by the Independent plant is from the smaller producers. J. H. Kemp has charge of the sampler at Idaho Springs. On Chicago creek, 7 miles from Idaho Springs, the Honest John M. & T. Co., J. F. Puchert manager, has eighty-six claims. The tunnel which was started one year ago is now in 1100 feet. In the next 200 feet they expect to tap the Maryville or Dunbarton vein. At the 1100-foot point they struck a vein with a pay streak 18 inches wide and the mill dirt 5 feet in width. The property is equipped with compressor and drills. Later on they expect to put in a water power plant and electric apparatus. M. W. Tanner is manager. The Waltham M. & M. Co., at Idaho Springs, are working their 20-stamp mill on dirt from their own mine. The mill when completed will have a capacity of 100 tons daily. The cyanide plant will be 75x110 feet, steel frame building and contain six 100-ton steel tanks. The furnace room will be 36x36 feet. The incline shaft is down 140 feet. They are putting in an electric pump.

Idaho Springs, Feb. 20.

(Special Correspondence).—The Old Town mine, in Russell gulch, is supplying J. G. Roberts, proprietor of the Jackson mill, with seventy-five to eighty tons of ore per day. The new 20-stamp mill of the Hudson Reduction Co., on Chicago creek, has a capacity of seventy-five tons per day. They are running mainly on their own ores from the Shafter mine, controlled by the Shafter M. Co. They have a shaft down about 790 feet and have 2000 feet of drifting. A. H. Roller is manager. Pike & Co. have a lease on the Little Mattie and have been running a drift 300 feet. On Fall river, 1 mile from Clear creek, the Lucania T. M. & D. Co.'s tunnel is in 1900 feet. The object of the tunnel is to get into the Russell Gulch district in Gilpin county. When completed the tunnel will be used for transportation of ores. They have 5000 feet to go. J. McColl is manager. The slimes plant which was erected last year to handle the slimes from the Gem Extension concentrating mill, and which has been closed down for some time past, has been leased to Palmer, Hampson & Strang, who are overhauling it and expect to start up in a few weeks. A 21-foot tailings wheel is being added to the plant, which already contains two vanners, one slimer and one Wilfley. The Pittsburgh Con. M. Co., operating the Brighton mines, 1 mile above Freeland, will erect a concentrating mill this summer. A large amount of ore has been blocked out and recently a good strike was made in the 400-foot level. The incline shaft is down 500 feet. A drift is being run to connect with some of the old workings of the Freeland mine, which will give them drainage facilities and do away with pumping. The mill will be erected on Fall river. D. Ellis has charge.

Idaho Springs, Feb. 18.

(Special Correspondence).—The Monarch tunnel, being driven by the Freeland D. & T. Co., is now in 3500 feet and has 1600 feet farther to go before striking the Freeland district.

Dumont, Feb. 18.

(Special Correspondence).—D. Kennedy, owner of the Centennial mine, is developing the mine and retimbering some of the stopes. He is hoisting fifteen tons per day. The mill is being operated one shift. As soon as the creek opens up so that a supply of water can be had he will run the mill full force. The Capital M. & T. Co., W. Cooper manager, has completed 161 feet of new tunnel, which shortens the old tunnel 750 feet. The compressor plant on this property will be started about March 1 and will operate two drills to drive the main tunnel at right angles to the formation of Griffith mountain 320 feet farther. With this tunnel it is expected to cut the Colorado Central belt at a depth of 250 feet below the Colorado Central present workings. It will make the depth of the tunnel 1650 feet below the apex of the mountain.

Georgetown, Feb. 18.

(Special Correspondence).—Work on the new mill of the Dives-Pelican is progressing as rapidly as weather will permit. The management expect to have the mill

in operation by the first of May. The new Rand compressor has recently been installed and is now furnishing air to the mine.

Silver Plume, Feb. 18.

W. Ballantyne is working the Silver Mountain and Ben Franklin lodes at Empire for the Benzie Investment Co. The work is carried on through the Empress tunnel of the Empire Tunnel Co.—Nelson & Co. are working the Silver Mountain vein.—The Silver Mountain mill at Empire is treating ore from the Benton mine at North Empire, worked by Bishop & Heckman, and the Mint lode at Empire, worked by P. Bue & Co.

#### Glipin County.

The 700-foot shaft being sunk by the Cashier G. M. & R. Co. on the Pittsburgh-Golden Wedge group, near Russell, is down 660 feet. B. L. Campbell is manager.—The Money Metal M. & Co. have taken a bond and lease on the Claudia J. and Millie B. lode claims, near Tip Top, in the Hawkeye district, from W. H. Kelley and M. Whalen. It is reported that they will put in an air compressor and a steam hoist.—L. J. Mountz has charge of the work on the Cronje and Cyrene claims, near Twelve Mile, in the Pine Creek district.

#### Gunnison County.

It is reported that the Maple Leaf M. Co., near Sillsville, will build a mill. The shaft has followed the vein down 300 feet and is to be sunk deeper. Heavier hoisting machinery is to be put in.

#### Jefferson County.

S. Guggenheim has presented the Colorado School of Mines at Golden with \$50,000 in cash for the erection of a hall of administration.

#### Lake County.

(Special Correspondence).—A new mill is to be built at the mouth of the Yak tunnel, near Leadville. The mill will be a reduction and concentration plant with a capacity of 200 tons a day.—The Murphy shaft on Rock hill is down over 400 feet.—Work has been resumed on the Triumph mine, on the east of Jonny hill, near Leadville.—Two of the six proposed new shafts on the western slope of Rock hill will be started by March 15. One will go down on the Parson, under the direction of F. H. Minard, and the other will be on either the Frank or the north half of the Mike, under the management of R. B. Stanton. Both shafts will go to the blue lime, or to 1000 feet.

Leadville, Feb. 21.

#### San Juan County.

The Detroit & Colorado M. Co.'s property on Sultan mountain, near Silverton, has been closed down for a time. L. L. Haines is manager.

#### Summit County.

The Lucky and Mineral Belt group, near Breckenridge, are being worked by the Beaver Creek G. M. Co., F. A. Yauger manager.—At Frisco the Copper Queen management is considering the erection of a concentration mill, near the Colorado & Southern track, and has started a new tunnel to cut the vein at greater depth. The new tunnel is so planned that ore from it could be run in the mine cars directly to the mill, in case the company decided to build it. It is expected that the tunnel will crosscut the vein, which it will follow, at about 200 feet from its mouth.—The Summit County Mining Exchange has been formed by A. E. Keables of Breckenridge to buy and sell mines in Summit county. D. H. Lawrence is examining and reporting engineer.

### IDAHO.

#### Cassia County.

R. N. Bell reports that the Sweetser-Burroughs M. Co., G. T. Burroughs, Jr., manager, has been dredging the Idaho river 30 miles southwest of Minidoka for ten years, with a suction dredge with a 10-inch nozzle. The hull is 30x90 feet, draws 3 feet of water and is handling 2500 cubic yards daily. A 125 H. P. vertical compound condensing marine engine supplies the power. From the suction the gravel is discharged into a 12-foot stationary sluice, set nearly horizontal, to check the velocity of the stream. From here it passes to two lengths of shaking sluices set at a grade of 1½ inch per foot. The sluices are 17½ feet long and 5 feet wide, shaking endways, with a 3-inch stroke. The bottoms are perforated steel plates, with ¾-inch holes ¾ inch apart. The coarse material passes to a rubber belt conveyor, which stacks it astern. The fine material with the gold is discharged into a distributing box, which feeds it to a set of sixteen inclined burlap tables set at right angles to the sluices and having an area of 1000 square feet, discharging over the side of the boat. The State Inspector of Mines reports that the operation is continuous and uninterrupted by the necessity of cleaning up, moving anchor lines, changing spuds, etc. The burlaps are taken up each shift and washed in a wooden tank, from which the accumulated gold and black sand are elevated automatically to the amalgamating room, where the gold is separated by barrel amalgamation. Wyoming coal has been used; but the company is experimenting with sagebrush, grubbed out by horse power and cut up with a bark mill for convenience in firing. The cost of handling gravel, including all charges, is 4½ cents per cubic yard.

#### Elmore County.

The Middle Boise placer claim, 14 miles from Rocky Bar, will be worked by H. D. Roberts with twenty men in the spring.—The Henry Clay mine, near Rocky Bar, is being worked by W. J. Bogard and R. Y. Bogard.—The Okobojia Placer M. Co., W. H. McNutt manager, will start work in the spring in the south end of Rocky Bar.—W. A. Nixon is developing the Commonwealth Hill mine, near Rocky Bar.

N. D. McLeod is working the Golden Cloud Con. mine, at Rocky Bar.—The Elmore mine is to be worked by I. E. Rockwell, of Bellevue.

#### Idaho County.

The Albertas claims, 3 miles south of Elk City, are to be worked by the Elk G. M. & M. Co., after being idle since last fall. J. A. McEachran is manager.—The Concord M. Co. at Hump is working fifteen men on the

Mother Lode No. 2, and has sunk the new Concord shaft 185 feet.—The Atlas Co., working west of the Concord, intends to sink 200 feet farther. R. C. Bishop is superintendent.—M. Dobbins is working the Lost Lake at Hump.

It is reported that the owners of the Little Giant mine, near Warren, will increase the milling capacity and put in an electric power plant. The mine now has a 5-stamp mill.—J. J. Jewell has charge of the Mayflower mine, near Warren.

#### Shoshone County.

The Montana-Idaho Summit M. Co. are working the Black Horse, 6 miles from Murray, and expect to ship lead ores. C. W. Betts and C. Manley have charge.

Although the operation of concentrators of the Cœur d'Alenes was interfered with by the inclement weather during January, the output amounted to 21,500 tons. The Bunker Hill & Sullivan shipped 5500 tons of concentrates and crude ores to the smelters. There was a slump in the output from the Morning mine at Mullan, due to the cold weather and the resulting inadequacy of the water supply, the output being 1500 tons. The loss in the production of the Morning is equalized by the copper shipments from the Snowstorm at Mullan, as 3800 tons were shipped to the Tacoma and the Anaconda smelters. The Federal M. & S. Co.'s Mace mines, the Standard and the Mammoth, produced 3500 tons of concentrates; the Tiger-Poorman 1500 and the Last Chance, at Wardner, 3000.

### ILLINOIS.

#### Jo Daviess County.

In a recent publication of the U. S. Geological Survey, H. F. Bain says that in the summer of 1903 there were in northern Illinois fifteen places at which mining or prospecting was being carried on vigorously. The Waters mine, at Galena, was for some time under bond to the Grant Reduction Works, which sunk several shafts, put up a concentrating mill and shipped about eighty tons of zinc ore before forfeiting the bond. The main output has been zinc ore. In earlier years galena was taken from this crevice, but the amount is not known.—The Little Corporal mine is one of the best equipped in the district and is making regular shipments of ore. The plant consists of an 80-ton concentrating mill, a crosshead pump, hoist, air compressor and two drills, the whole driven by gasoline power. The present workings are connected with the surface by a shaft 110 feet deep. At the time the mine was visited the lower drift was 400 feet long. The opening varies from 8 to 12 feet in height, being closed usually by a firm cap rock in which the crevice is marked by a mere line. In places it could be seen that above the timbering there were chimneys connected with the opening. The drift varied in width from 6 to 16 feet. The predominant ore mineral is blende, very little galena or carbonate being present. The present work is 20 feet below the plane of permanent water, but is within the zone of oxidation, as shown by the brown color of the rock and sand. The usual thin film of iron sulphide occurs between the blende and the rock, and occasionally large crystals of pyrite occur. For this region, however, the ore is unusually free from iron sulphide. The concentrates are said to run from 50% to 60% in zinc and 2% to 4% in iron. The tailings are unusually clean and the ore does not need roasting and cleaning. As many as fourteen tons of concentrates are said to have been produced in a single mill shift. The mill started in July, 1903, and has run more or less steadily since. The flow of water is steady, but the amount is not known. In Vinegar Hill township there are many old workings and the area has produced a large amount of lead. Efforts have been made to reopen several of these mines, among which is the Vinegar Hill mine. This is in a small ravine running into Galena river, the top of the shaft being 33 feet below the base of the shale. The crevice runs east-west and has yielded galena at a depth of 29 feet. A new shaft is being sunk and a drift is being run to the east 10 feet below the old workings. A gasoline engine for power was in operation when the plant was visited. At the Fox River Valley mine the old workings on an east-west crevice are being reopened. Two shafts, one 95 feet and the other 65 feet, are open. Both galena and blende have been found in small quantity. The Oldenburg mine, near Galena, was not open in the summer of 1903. There are two shafts, the lower 100 feet and the upper 140 feet deep. This mine is along an east and west crevice, or, rather, along two nearly parallel crevices, which unite toward the eastern part of the mine. The ore body is in a vertical sheet and is an example of the honeycomb deposits. The thickness of the sheet varies from almost nothing up to about 30 feet and has been mined for about 800 feet in an east and west direction. A small amount of lead is present. Where small north and south crevices cross the main crevice there are usually larger and richer deposits of ore. The mine of the Northwestern Lead & Zinc Co. is near the Wisconsin boundary, not far from the Chicago & Northwestern Railway. The mine, which was visited in the summer of 1904, was developed in the preceding winter. The shaft, which is 92 feet deep, is at the base of the slope at the head of a small tributary of the Galena river. The workings extend east and west for nearly 200 feet. The ore consists of thin sheets of blende developed along the partings of the rock and minor amounts of breccia found in connection with some northward-pitching fractures. Very little iron pyrite shows in the mine. The workings are below water level, though oxidation extends down almost to them. There is a new and well-equipped mill on the property. The California, or Sand Prairie mine, is being opened by the Royal M. Co., near the Mississippi river, at the extreme southern edge of the district, in a small ravine. In the vicinity are a number of old lead diggings, which were formerly worked by long adits driven in from the edge of the bluff. These mines were the scene of great activity from 1849 to 1855, and at that time acquired the name of California diggings. The Royal M. Co. has three shafts on an east-west crevice about half way up the slope of the ravine which parallels the vein. The Wishon mine, north of Elizabeth, was an important producer of lead about 1865. In 1902 the old workings were reopened in a search for zinc and a new shaft was sunk 145 to 150 feet in depth. This was closed

at the time the place was visited. The workings are developed along an important east-west crevice marked by old shafts for a distance of a mile along its course. The ground shows thorough oxidation, and galena was the only mineral seen. It occurs in small pieces in tight crevices, the remaining ore evidently having been removed. The Apple River mine is north of Elizabeth on a crevice which has been an important producer of lead. In the summer of 1903 an old shaft was being pumped out, but the workings were not sufficiently advanced to permit of any examination. The Skene mine in 1904 was reopened by the Elizabeth M. & M. Co. It is on a crevice running N. 83° E. It shows well-defined pitches to the north and south at a depth of 96 feet. The mine has been developed about 1200 feet along the south pitch, with crosscuts to the north. The work is below present water level, but is entirely in oxidized ground. The ore consists of nearly clean galena. Minor amounts of pyrite are found, both as the usual film separating the galena from the rock and in distinct balls and crystals. No carbonate of zinc occurs and only a very few small pieces of blende. The ore is mainly in the south pitch, but numerous small flats and verticals run off into the core between the pitches, and possibly the whole of the core may be mined. There is no evidence that the galena in this case is a secondary concentration, and the amount of it, if it be original, is notable. Between May and August over 600,000 pounds were shipped without any cleaning facilities other than hand jigs. The Queen mine is near Elizabeth. The Vista Grande is a small lead mine near Scales Mound with a shaft 115 feet deep. The Peru, or Black Jack, is a well-equipped property, not now in operation. Between the years 1876 and 1882 it was a steady producer, shipping ore regularly to the Illinois Zinc Co., with which its owners were affiliated. Recently a new mill was erected, and the mine was pumped out and examined preparatory to resuming work; but apparently the ore reserves were unsatisfactory, as the plant has been closed down. The superintendent is H. Ragge. The ore is blende, occurring intimately mixed with iron sulphide. Near the top of the workings, 45 feet below the surface, cubes of galena ¾ inch in size were found plentifully sprinkled over the blende. The ore occurs in thin sheets in the pitches and in flats along bedding planes.

### MISSOURI.

#### Jasper County.

(Special Correspondence).—The Hazel M. Co. of Webb City is making improvements in their property and will put in a new boiler, steam hoister and pump.—J. W. Brooks & Co. of Joplin, working the Schifferdecker land at Chitwood, have opened up a good mine at 145 feet, and will begin putting up a new 100-ton mill this spring.—Luke & Brown of Alba have a lease on eighty acres of mineral land and will commence prospecting by drilling.—The General Lead & Zinc Co. of Webb City, owning forty acres of land near Carterville, will build a new 100-ton mill this spring. A fine body of ore has been developed at a depth of 160 feet.—Holmes, Cape & Rodgers M. Co. of Joplin will build a new 100-ton mill on their 120-acre lease at Badger as soon as the weather will permit.—Mitchell & Huffman of Galena have opened up a good prospect on the Galena Lead & Zinc Co.'s ground near Galena.—The Bullfrog mine, near Joplin, owned by the Mattes Bros. of Joplin, has been sold to a Rochester, N. Y., syndicate for \$75,000. The property will be managed by C. E. Hart of Joplin.—The Hancock M. Co. of Joplin has struck a body of ore by drilling on the Murphy land southeast of this city. A mill will be erected upon the completion of the shaft. A. T. Bragg of Tuscola, Ill., and J. E. Hancock of Hamilton, Ohio, are interested.—C. Mauby and J. Jones have struck zinc ore in sinking a shaft on the Kiheka tract southwest of Carthage. Silicate was struck at 2 feet and was found continuously to a depth of 58 feet, when a good body of zinc ore was struck.—A new \$12,000 mill, built by the American Zinc, Lead & Smelting Co. of Webb City, is nearly completed on the forty acres of land north of the Get There lease near Carterville.

Joplin, Feb. 19.

### MONTANA.

#### Flathead County.

M. Downey has charge of the work on the North-western claim on Callahan creek, 3 miles from Troy. A compressor has been put on the property and a shaft will be sunk with air drills.—It is reported that Larson & Greenough will put a compressor and other mining machinery on the B. & B., near Troy.—The Rustler M. Co. is working the Snowshoe mine, 18 miles south of Libby. They have bought the Chinook from J. Z. Clark and F. Wegner.—P. J. Brophy, J. O'Rourke, D. J. Hennessy, A. J. Campbell, T. M. Hodgins, M. Finlan and T. J. Walsh have formed the Libby Placer M. Co. at Lewiston and taken over the Howard placers, 25 miles south of Libby. In the preliminary work of acquiring water rights, perfecting titles and prospecting, they have expended \$40,000. The water from five creeks will be used in washing the gravel, and the plant is equipped with a water power derrick for handling big boulders.

#### Granite County.

D. T. Conkling is superintending the driving of a tunnel to reach bedrock on placer mines on Stony creek, 16 miles west of Phillipsburg. H. Kaiser of Phillipsburg is interested.

#### Lewis and Clark County.

Thirty stamps began dropping at the Bald Butte mine, near Helena, on February 15. J. Edgerton is secretary-treasurer at Helena.

#### Madison County.

C. E. Lentz, president of the Lentz Gold, Copper & Silver M. & R. Co., 7 miles south of Bear gulch, says that the mine is developed by 400 feet of tunnel and 200 feet of upraises. They expect to put up a hoisting engine, as they intend to sink a shaft.—It is reported that the Watseca, Bonanza and Champion mines at Rochester are to be worked through a new 1000-foot shaft to be sunk on the Bonanza. The 600-foot shaft on the Watseca will be unwatered if it is not drained by the new shaft.

## NEVADA.

## Esmeralda County.

C. A. Montgomery is to build a mill at Beatty's, on the Amargosa river.—The old Amargosa mine, which was a shipper in the '60s, is to be reopened and a new mill put in.—H. L. Frank of Butte, Mont., who has mining interests in Goldfield, is preparing to put in a mill capable of handling 250 tons daily.

The reduction plant built by the Goldfield Reduction Co., at Goldfield, is nearly completed and stamps will be dropping in two weeks. All of the machinery for the mill is on the ground and will be installed. There will be ten 1240-pound stamps put in at first, giving a capacity of thirty tons daily. Later a complete cyanide plant is to be added to the equipment and as conditions warrant the capacity of the mill will be increased. M. C. Gardner, Jr., is in charge. It is reported that H. L. Frank of Butte, Mont., will build a 40-stamp mill at Goldfield. G. R. Potter is manager, and F. Enzensperger superintendent of construction.

The railroad fare from Reno to Tonopah is \$17.15; the stage fare from Tonopah to Goldfield is \$4; automobile fare from Tonopah to Goldfield is \$6; hauling by mule team, Tonopah to Goldfield, per ton, \$20; furnished rooms in adobe houses, \$1.50 per day for one person, \$2 for two if they occupy one bed; miners, \$4 to \$4.50 a day; laborers, \$4 a day; cooks, \$6 a day and board; printers, \$4.50 a day; carpenters, \$6 a day. Goldfield is in a mountainous desert 45 miles from the California line, at an altitude of 5000 feet. Hay sells at \$55 a ton; lumber, \$70 per thousand feet; kindling wood \$18 per cord; kerosene, 60 cents a gallon; fresh milk, 25 cents a quart; sugar, 10 cents a pound; hoots blacked, 25 cents; the MINING AND SCIENTIFIC PRESS 25 cents per copy.

## Lincoln County.

The Bamberger-De Lamar M. Co. at De Lamar, F. P. Swindler superintendent, will add a new 750-ton slimes plant to the present mill equipment. At the mills is a large tailings dump which contains values worth saving, and it is the intention to work them over. This dump was formed when De Lamar operated the dry process mill.

The Black Hawk M. Co. has started work on the Buster mine at Searchlight. They will put up a 10-stamp mill when they have made provision for a sufficient water supply. Two 85-foot shafts have been sunk. C. E. L. Gresh has charge at Searchlight.—A. M. Jones and C. Anderson have bonded the Sazerac and Winona claims at Dupont from G. H. Hamstadt of Manvel.

## Nye County.

J. Griffin and H. Cutting have sold the Utopia mine at Lone Mountain to the Anglo-Nevada M. Co.—In his report to the Montana-Tonopah M. Co., working the Rye Patch plant at Tonopah, Manager D. B. Gilles recommends that a double-drum hoisting engine be purchased and that the ore bin capacity be enlarged.

O. S. Swanson of Spokane, Wash., and C. H. Huber of the Coeur d'Alenes, Idaho, have bonded the Hummer claim near Tonopah, Nevada, for \$25,000.

Regarding the Kawich district, E. W. Tremont of the Eureka Prospecting Co. says, in the Eureka Sentinel, that Goldreed is on the east side of the Kawich range, 40 miles south of Reville, and 180 miles south of Eureka. There are several large quartz ledges cutting the porphyry formation. The trend of the ledges is northwest and southeast, dipping to the east, but not enough development work has been done to show the actual dip. The ledges run through the range for 4 miles to Nixon on the west side. The Goldreed M. Co.'s group comprise 26 claims, and 322 claims have been recorded, while there are probably as many more that had not been put on record. The deepest hole in camp is the Discovery shaft, which the company has sunk 50 feet and is now crosscutting on the ledge. The outcroppings are strong and well defined, and in some places carry high values in free gold. Development work has been retarded by lack of water. On the discovery of water the immediate future of the camp depends, although work will be prosecuted even if water has to be hauled in wagons until development justifies pipelined water from a distance. Several are sinking wells in different places.—A. Dees of Eureka and J. Walters of Huntington are partners in a well 12 miles east of Goldreed, and they struck water at 7 or 8 feet, but are going deeper. Many miners are working on leases from the Goldreed Co. Each lease comprises 150 square feet. The company reserves every alternate lease, in addition to 600 square feet surrounding the Discovery shaft. The life of a lease is 9 months, with the privilege of prospecting for 30 days. At any time within 30 days a lease may be thrown up and another one taken. If, however, at the end of 30 days a man decides to hold his lease, his contract is good for 8 months longer. The terms run from 20% royalty on \$100 ore to 40% on \$750 ore and up. The town of Goldreed has laid out has three principal streets and several cross streets. All the houses are canvas. There are 2 restaurants, 2 lodging houses, 8 saloons and 1 store. Meals are 75 cents and up; cots \$1.50 a night; water \$6 a barrel, and cedar wood \$20 a cord. The health of the camp is good. The climate is very similar to Eureka, but there is not so much snow. Miner's law prevails, and at a recent meeting of the miners wages were fixed at \$4.50 for eight-hour shifts. It was decided that no Japanese or Chinamen be allowed in Kawich. Goldreed may be reached by way of Eureka: Eureka to Fish creek 18 miles, Fish creek to Willow creek 20 miles, Willow creek to Hicks' 15 miles, Hicks' to Moore's 16 miles, Moore's to Hot creek 18 miles, Hot creek to Tybo 12 miles, Tybo to Reville 40 miles, Reville to Goldreed 40 miles. Total 179. One may go from Hot creek to Warm springs (15 miles south of Tybo) and then to Reville mill (12 miles west of Reville) and shorten the distance 12 miles by cutting out Tybo and Reville. There is water at all the above stations, hut meals, and hay and grain may be had only at Fish creek, Willow creek and Hot creek.

## Washoe County.

The Salt Lake & Reno M. & M. Co., J. W. Stolly manager, is developing a gold property 10 miles north of Peavine, north of Reno.

## NEW MEXICO.

## Grant County.

The machinery for the Century Co. has been all placed on its claims in the Lordsburg district by Wm. Davis. The shaft on the principal claim is being enlarged and timbered. After that work is completed the shaft will be sunk deeper. Water for the plant is being pumped out of the shaft.

## OREGON.

According to the United States Geological Survey reports, the mineral output of Oregon for 1903 was:

Gold	\$1,412,208
Brick and tile	425,544
Mineral waters	357,559
Coal (bituminous)	221,031
Quarry products	138,007
Gas	89,305
Silver	62,211
Gas coke	18,896
Coal tar	5,040
Platinum (110 ounce)	2,080
Copper	1,930

Total \$2,723,930

Lead (with South Dakota, Texas and Alaska)	\$ 149,566
Borax (with California and Nevada)	601,400
Raw clay products—kaolin and ball clay (with Arizona, Connecticut, Iowa, Maryland, Massachusetts, Michigan, New Hampshire, North Carolina, North Dakota, Utah, Virginia and Tennessee)	124,602

Total \$ 935,568

Ammonia (with Colorado and Washington), pounds	211,465
Steel (with Michigan, Missouri, Wisconsin, Minnesota, Colorado and California), long tons	236,891

## Baker County.

The Indiana copper property, 20 miles from Baker City, is being developed by F. W. Messner Sr., who has his shaft down 320 feet and is drifting on three levels.

Two rapid drop stamp mills are to be put in the Oro Fino mine, near Greenhorn.—W. L. Vinson has put in concentrators to save the black sand and fine gold at his placers at North Fork.—The Daines M. Co., over the hill from the I X L, are prospecting the Belcher vein. F. Daines has charge.

Manager Kelly, of the I X L mine, near Greenhorn, intends to stop underground work for a time because of the light pumping capacity of the plant, it being insufficient to handle the water. The company may be reorganized and may put in a sinking plant.

## Douglas County.

C. C. Mathews, superintendent of the Oregon Securities Co., in the Bohemia district, reports that driving on the Champion vein is progressing rapidly, and that the ore encountered continues to improve. The mill was started, but the ice formed on the concentrates and it was closed down until the weather moderates.

## Lane County.

The 40-stamp quartz mill at the Lucky Boy mine, at Blue River, has been closed down and will remain closed for several weeks on account of the fire. L. Zimmerman, president of the Lucky Boy M. Co., who was at the mines at the time of the fire, left immediately for Portland to replace the machinery.

## Grant County.

N. Berkeley may build a mill on the Buffalo-Monitor mine near Granite.

## Josephine County.

The Grants Pass Miners' Association intends to oil the 45 miles of wagon road between Grants Pass and the Waldo copper mines. Under existing conditions the road is impassable to loaded wagons during the winter months, and, as a result, the smelter can not be operated except in summer, when the hauling in of coke can be done on a scale sufficient to keep the plant running.

C. D. Crane, manager of the Lucky Queen mine at Winona, reports that the new 10-stamp mill is almost completed. It will be run by a 15-inch water wheel under a head of 31½ feet, from a ditch from Jump-off-Joe and Shorthorn creeks. It is intended to have the mill running by March 1. In the mine 2000 feet of tunnels have been run, blocking out considerable ore, which will be hauled 1 mile to the mill in wagons until the aerial tramway is completed. The postoffice will be discontinued on February 28, being superseded by the rural mail service on February 15 on the route from Grants Pass by way of the Jump-off-Joe valley.—It is reported that E. F. Terry will equip the Carr & Ferry placer on Silver creek, near Grants Pass, with hydraulic machinery.—A. H. Gunnell and H. E. Foster may build a 10-stamp mill on the Oregon Belle mine, near Jacksonville. Plans and an estimate have been prepared by F. E. Willett of Grants Pass, who recently completed the mill at the Opp mine.—The Enterprise M. Co. has started work on the Homestake mine, ½ mile north of Woodville, under the superintendence of F. Trowbridge, formerly with the Elkhorn mine, near Baker City. He will put in electric power so soon as the Gold Ray and Grants Pass electric line is completed.

## SOUTH DAKOTA.

## Lawrence County.

The Victoria M. & M. Co., G. S. Jackson of Deadwood manager, has started grading for their new mill and cyanide plant at Maurice station on the Spearfish branch of the Burlington road.—The Mainstay M. Co. at Keystone has completed the foundations for the vats of the cyanide plant to treat the product from its 30-stamp mill.—The Lucky Strike G. M. Co. has completed its payment on its properties in southern Lawrence county. C. A. Allen of Deadwood is manager.—The Golden Elk M. Co., working in the Nigger Hill district on the boundary line between South Dakota and Wyoming, will put in an air compressor and a sawmill. E. B. Sager of Deadwood is president and F. E. Wharton of Lead secretary.—At the annual meeting of the Black Hills Anaconda M. & M. Co., W. F. Cochran was elected president, C. C. Mourisse vice-president, J. Donaldson secretary and W. W. Steinmetz treasurer, all of Chicago, Ill. G. A. Karr, general manager at Hill City, was instructed to negotiate for hoisting machinery. The

property of the company consists of a large acreage in Central Hills. Development has been going on for over a year.

C. W. Merrill, metallurgist of the Homestake M. Co. at Deadwood, stated before the meeting of the Black Hills Mining Men's Association that the cost of crushing ore in the Amicus mill (240 stamps) was 18 cents per ton. The fineness crushed to is equivalent to 35 mesh, a slot screen being in use. Sizing tests show the pulp to consist of: 28% coarser than 100 mesh, 18% between 100 and 200 mesh, and 54% finer than 200 mesh.

## Pendleton County.

F. Herbert, president of the Clara Belle M. Co., working the Clara Belle mine near Oreville, intends to sink a new shaft, as the present one is out of line and unsafe because of caves in adjacent stopes. The Clara Belle has a 10-foot fissure vein in well-defined walls in the slate. The two stamps of the Tremain mill are crushing ten tons of free milling ore per day.

## Custer County.

The Hartford mine, near Custer, owned by C. C. Cray, J. C. Spencer and C. W. Carpenter estate, is to be cleaned out, the shaft retimbered and the property put in shape.—The Leroy G. M. & M. Co., near Custer, has struck good ore in a drift from the shaft at 90 feet depth. Samples of the ore were sent to the Omaha & Grant smelter, giving returns up to \$118 in gold per ton. The vein is 3½ feet wide. The ore is being stoped and will be shipped as soon as a carload is broken. F. H. Cook, president, has made arrangements for the treatment of a carload at the smelter in Omaha.

## UTAH.

## Plute County.

H. C. Lawrence, manager of the Sevier Con. mine near Kimberley, says that the mill is handling fifty tons a day and the loss in the tailings does not exceed .002 of an ounce in gold or .22 of an ounce in silver. The ore treated carries \$16 to the ton. About 25% of the gold is saved on the copper plates, while the balance is extracted by cyanide. Forty men are at work.

## Salt Lake County.

The Bingham Con. M. Co. will reduce the shipment of ores from its own mines to make room at the smelter for 200 tons of ore daily from the Boston Consolidated property, and also for concentrates from the Newhouse Mines & Smelters Co., whose mill is ready to begin. The Bingham's Commercial mine yields ores which contain satisfactory copper-gold-silver values and an excess of iron, and the management feels that this ore will be sought for its fluxing qualities. When sufficient iron can be obtained from custom ores to make a proper smelter charge it is to be expected that the commercial shipments will be reduced, and that the mine may be closed down for brief periods. The development work of the past two or three years has blocked out a large tonnage of ores in the Daltou & Lark, Miner's Dream and Brooklyn mines, and of late a considerable proportion of the company's output has come from these properties. In view of the fact, however, that the Mascotte tunnel, now being driven by the company, will cut under these mines, several hundred feet below their deepest workings, six months to a year hence, and provide an avenue through which their ore can be extracted at a saving of \$1 per ton, it is naturally preferred not to draw heavily on their resources until this tunnel is completed.—H. M. Adkinson, manager of the New England Gold & Copper Co.'s mines at Bingham, reports that the crushing capacity of the mill is to be increased and equipment added that will double the capacity of the plant, or up to fifty tons a day.—Manager H. S. Joseph of the Silver Shield mine of Bingham recommends that the company erect a concentrating plant in the spring to handle the milling ore and put it into a commercial product.

## WASHINGTON.

## Chelan County.

C. Rubin, superintendent of the Crown Point M. Co., at the head of Railroad creek, 18 miles from Lake Chelan, reports that the vein carries molybdenum, gold and copper, also vanadium.

A number of copper properties around Lake Chelan, Chelan P. O., promise well. A 600-foot shaft has been sunk on the Holden and drifts have been run at each 100-foot level. A 15-mile railroad has been completed from the lake to the mine and a matte smelter is being put up on the lake. H. G. Stilwell is developing the Grand View, adjoining the Holden property.

## Ferry County.

Manager A. I. Goodell has started the third furnace at Northport to handle the increased tonnage being received. The Mountain Lion, at Republic, is shipping fifty tons weekly, having contracted for the treatment of 200 tons; the First Thought mine, at Orient, is shipping seventy-five tons per week, and the Copper King, near Chewelah, is sending a car each week.—H. Young, manager at the Fortune Group M. Co., near Orient, has started work at the mine and says that the shaft on the Fortune claim, which is now 40 feet deep, will be continued down to the 100-foot level, when the ledge will be crosscut. The ledge is between serpentine and granite. The Fortune has shortened the distance to its mine by building a road connecting with the Sand creek road and thence down to Rockett.

## Skagit County.

A company has been formed by H. N. Anderson, Aberdeen, Chehalis county, president; A. S. Austin, Aberdeen, vice-president; W. W. Butler, secretary; I. M. Anderson, Aberdeen, treasurer; E. C. Miller, Seattle, general manager, to manufacture Portland cement at Cement City, on the Great Northern Railway, in Skagit county, where a townsite is being platted. The plant is to have a capacity of 1200 barrels per day, and is to be run by water and electric power from the Skagit river.

## Snohomish County.

The Monte Cristo and other mines shipping arsenical

ores to the smelter of the American S. & R. Co. at Everett have demanded pay for the arsenic in the ores, but have been refused. There is talk of the larger shippers building a furnace near their properties to roast the arsenic out before shipping to the smelter. The smelter is said to be shipping 200 tons of arsenic monthly. The arsenic ores treated at this plant are mainly arsenopyrite, containing about 14% of arsenic, 0.7 ounce of gold and 3 ounces silver per ton. The by-product plant for the condensation and collection of the white arsenic consists of a long brick flue, 20 feet high, connecting the Wetley mechanical six-hearth sixty-ton roasting furnace with the dust chamber, which is 5 feet high, and covers an area of 125x150 feet. This chamber is built of 4-inch brick walls and is divided into four parts, so arranged that by the use of dampers any one section can be cut off from the other and the condensation carried on continuously. The arsenical compounds in the ores are decomposed during the roasting, and are transformed chiefly into volatile arsenious oxide which is condensed from the fumes.

#### Stevens County.

The Last Chance mine, on Deep creek, near Republic, has been bought for \$43,000 by L. P. Larsen of Northport, who has sold it to the Jupiter Lead Co. of Joplin, Mo.

### WYOMING.

#### Carbon County.

The Cascade Copper Co. has resumed work on its tunnel, near Grand Encampment, under the superintendence of W. Suttingham. He will start drifting on the ore from the bottom of the 100 foot shaft. The two-compartment shaft of the Blanche C. M. Co. has been sunk 140 feet and will be sunk to a depth of 200 feet before drifting is started. A. H. Crow is superintendent.

The Anchoria mine, near Dillon, is to be equipped with a 40 H. P. boiler, a 6x8 hoisting engine, ore buckets, a No. 6 Cameron pump, wire cable, steam drill, ore cars, tracks and blacksmith shop.

#### Utah County.

The Pittsburg-Salt Lake Oil Co., A. V. Taylor of Salt Lake City, Utah, manager, will build an oil refinery at Spring Valley with a capacity of 1000 barrels a day. Of seven wells that have been sunk by the company five are producing at the rate of 1000 barrels per day. Plans have been made for putting up a 35,000-barrel capacity tank. The company expect to sink twenty wells. Analysis has shown the Spring Valley petroleum to contain 27% gasoline and benzene, 25% kerosene (water-white 45° B., 145° flash, 172° fire), 7% signal and headlight, and 41% lubricating stock carrying 18% paraffine. The crude oil is light green in color.

### FOREIGN.

#### AUSTRALIA.

##### Queensland.

At the Mount Morgan mine prospecting by diamond drills is being pushed ahead, and the overburden is being rapidly removed by the steam shovel. The new underlie shaft has reached a depth of 174 feet. The country is improving slightly as depth is attained, but great care has still to be exercised in timbering, etc. The shaft has penetrated the Luda workings. The excavations for the new smelters are well advanced, and the erection of the brickwork will soon be under way. These excavations will encroach on the site of the small water jacket, until recently in commission as a scavenger and experimental furnace, and smelting operations have been stopped and the furnace will be taken down. The returns from the Mount Morgan mine show the output of gold from ore chlorinated during December was 12,498 oz. 12 dwt. from 16,713 tons of ore treated. This increased average yield is partly due to gold recovered by a general cleaning up and partly to some richer ores recently uncovered by the steam shovel having been sent to the works for treatment. During the month 20 tons 4 cwt. of copper precipitates were collected. These precipitates are of slightly lower grade than usual, the 20 tons 4 cwt. only representing 14 tons 15 cwt. of metal. The smelter, which only ran for a short period, treated 123.6 tons of copper ore and by-products for a yield of 6 tons 8 cwt. 3 gr. of copper and 76 oz. 4 dwt. of fine gold. The Mount Morgan tailings, on the areas adjoining the Mount Morgan company's property, are to be again worked. Arrangements have been made by W. Usher, of the Old Union mine, Crocodile, with Arnold, Lowry & O'Connell, who have for some time been working sand claims on the Dee river, to erect machinery for the purpose of retreating the tailings on their holdings. Careful assays of the tailings have been made, which point to the conclusion that not only are the tailings worth working as heretofore for their copper contents, but that they will also pay to treat for gold. Early in the new year, therefore, Mr. Usher proposes to erect a 10-head stamper battery, with Berdians and Wilfey tables, to recrush and treat all the tailings which have accumulated in the claim. The gold contents may not be very considerable, but by the introduction of labor-saving appliances the new proprietors are convinced that there is money in the venture. A sand pump will be erected to pump the tailings into the battery hoppers, and by this means the cost of handling the material will be so reduced that a very small percentage of gold will pay the working expenses. Formerly the battery screens were much coarser than those used at present, and it is anticipated that, by recrushing the tailings, a further percentage of gold will be secured by this means. Mr. Usher also proposes to treat the tailings and water for their copper contents on a much larger scale than formerly, and for this purpose intends to erect a powerful centrifugal for pumping the water into the precipitating vats and chutes. Heretofore ores carrying from 1½ to 3½ oz. gold per ton have yielded all but 20 gr. to 26 gr. by chlorination. Low-grade ores, going 12 dwt. per ton, gave an extraction of from 93% to 94%. Crushing and roasting has cost about \$2 per ton, chlorinating \$1.50 and mining \$2 per ton. The average of the ore treated is between 11 dwt. and 12 dwt. of gold per ton. The Mount Morgan Co.'s new dam, on the Upper Dee river,

has a capacity of 220,000,000 gallons. The reservoir is in some parts 300 yards wide, and is 30 feet deep at the weir, costing \$20,000. The weir was completed four years before there was sufficient rainfall to fill the reservoir, but it has now been practically full for some time.

### BRITISH COLUMBIA.

#### Atlin District.

At Atlin A. C. Hirschfeld is manager of a company interested in developing recent magnesite finds. Regarding mining on Pine creek, A. Carmichael in the Atlin Claim says that the Pine Creek Power Co., F. T. Blunck president, and M. W. Loveridge hydraulic superintendent, have been working the south benches of Pine creek, moving 130,000 cubic yards of gravel in 1904. J. M. Ruffner, manager of the North Columbia Hydraulic Co., purchased the Eastern leases from the Eastern Hydraulic M. Co., together with ditches and plant. The Caledonia group, worked under the management of F. H. Brackett and owned by the Atlin and Willow Creek M. Co., produced \$15,000 during the past season. On Gold Run the British-American Dredging Co., O. T. Switzer, general manager, operated their Bucyrus continuous bucket type dredge during the summer. On Spruce creek the Spruce Creek Power Co., with E. T. Blaine as manager, and H. Haslett, hydraulic superintendent, acquired interests of the Con. Spruce Creek Placers, Ltd., and put in a plant. The British Columbia Dredging Co., A. C. Denniston, general manager, at Blue Canyon, built a 7½-foot open connected type, elevator dredge. A right-of-way 7½ miles long was cut out, and a pole line erected, to connect with power line from Pine Falls to Gold Run. On Boulder creek the Societe Miniere de la Colombie Britannique, H. Maluin, manager, is worked by drifting and hydraulic mining. In 1903, under the management of J. H. Black, in nine months 45,000 cubic yards of gravel were moved, of which 15,000 cubic yards were elevated and sluiced, from which \$60,000 was won. In eleven months in 1904 they earned \$74,000, the largest amount won from any single operation in the district. The steam hoist consumed 700 cords of firewood and the mine used up 2600 sets of timber and 25,000 lagging. On the company's property, hydraulic mining was also engaged in, under the superintendence of J. Fall, which brought the total yield close on \$90,000. On McKee creek the Amalgamated McKee Creek Co., C. M. Hamshaw, manager, has acquired the interests of the Atlin M. Co. and the McKee Creek Con. Co. They uncovered 8000 square yards of bedrock, the gravel yielding \$42,000 in gold. Including the yield of ground let on lays, the company report an output of \$52,500. To more economically work this property, the management propose to put in a steam or electric shovel plant, construct an electric tram line to Atlin Lake, 2½ miles distant, and there, with the unlimited dump and supply of water available, wash the pay gravel. At Birch creek, the Atlin Lake M. Co., under the management of B. Williams, washed 30,000 cubic yards of gravel and won \$12,000 in last summer's work. Besides this company, there were twenty placer miners working. On upper Otter creek, the Otter Creek Hydraulic Co. completed the installation of a complete plant and are opening up the mine. It is reported that Carmichael & Moran will work it next season. On Wright creek, Davis, Gierke, Hodges and Kershaw have opened up the ground owned by the English Counties Hydraulic Syndicate, C. D. Mason, manager. They put in a small hydraulic plant, which includes an automatic cableway for handling stones. The Ruby Creek Mining Partnership, on Ruby creek, under superintendence of R. McKay, made an open cut, 200 feet long, and sunk a shaft to bedrock struck 47 feet from the surface. From the bottom of the shaft a cross-cut was driven 40 feet, showing pay gravel 25 to 30 feet in depth and the crosscut as far as driven failed to reach its limits. On Bull creek, the Bull Creek Syndicate built 2500 feet of ditch and 400 feet of bedrock flume; it has 4500 feet of loose lumber on the ground, and washed 10,000 cubic yards of material and cleaned 585 square yards of bedrock. A. Carmichael is manager. Consolation creek, whose source is in the same range as that of Boulder and Ruby, but which flows into Gladys lake, in the Teslin watershed, was prospected last summer by O. C. Solt and J. M. Buchanan, who staked discovery on September 14. A stampede followed. Miners working there now speak with confidence of the future of that district.

The United States Consul at Victoria reports that it has been found impossible to successfully work hydraulic mines in many portions of British Columbia at the prices paid for white labor, and an effort is to be made again next season to introduce Chinese labor in the hydraulic mines at Atlin. A few years ago a number of Japanese were taken into the district for this purpose, but the determined opposition of the local miners' union compelled the mine owners to abandon their intention. Since the conditions have considerably changed, there being far fewer white miners in the district than formerly, while it has been clearly shown that it is not possible to profitably operate many of the Atlin hydraulic properties without largely reducing the cost of labor. Under these circumstances it is probable that there will be less opposition to the contemplated employment of Chinese labor, particularly as it is proposed to increase the wages of white miners now in the district, who will be employed as foremen or overseers. In other cases the labor problem is being solved by dredging.

#### Boundary District.

Manager J. P. Graves, of the Granby property at Phoenix, expects to get the two furnaces ready for blowing in by July 1. Work is being rushed, and the mine management will be ready to install the additional equipment when it arrives. Then the monthly capacity of the smelter will be from 70,000 to 75,000 tons.

Assets of the Winnipeg Mines, Ltd., in Wellington camp, have been sold for \$2500 to satisfy the labor liens against the property, which have remained unpaid for more than a year, to W. T. Hunter, representing himself, C. D. Hunter, J. Hunter, W. S. Macy and A. B. Hodges. Five thousand feet of development work has been done, including a 350 incline shaft and much drifting. The buildings are comparatively new, and the air

compressor, boiler, pumps, etc., are in shape to do business.

The E. P. U. mine, at Providence, is working twenty-one men.—The Goldfinch mine, belonging to M. F. Madden, has started operations.—J. F. McAllister, superintendent of the British Columbia Copper Co.'s smelter at Greenwood, has been in New York to confer with the board of directors respecting the proposed enlargement of the plant.—A. D. McPhee, superintendent of the McKinley mine, Franklin camp, north fork of Kettle river, says that the glory holing system of mining will be used at the McKinley when operations are resumed in April. The ore zone is 352 feet wide, and has been opened up by surface cuts and stripping.

#### Kootenay District.

B. Crilly, former superintendent of the Great Northern mines, and interested in Poplar Creek mines, states that the Great Northern mines will put in an additional ten stamps, making twenty stamps in all. Forty stamps will be put in on the Lucky Jack and Swede at Poplar creek.

A ½-mile tram will be built from the Swede group to Poplar.—On the Broken Hill, on Rapid creek, a stamp mill will be put in.

#### Nelson District.

Nickel in commercial quantities has been found on the Yankee Girl mine, near Ymir. An assay for nickel showed 5.1%. This is the first discovery of nickel in commercial quantities in British Columbia. At present there are no smelting facilities nearer than Sudbury, Ontario. The owners of the Yankee Girl are communicating with the smelters there, and it is probable that a trial shipment will be made. The Sudbury ores, which are the chief items in the world's supply of nickel, average 3% nickel.

#### Southeast Kootenay District.

It is expected that smelting at the new plant of the Sullivan Group M. Co. at Marysville will start with the first furnace about March 1. The second furnace, a duplicate of the first, with a capacity of 200 tons of lead ore daily, is expected to be running March 15. At the mine, near Kimberly, B. C., thirty-five men are at work on development and stopping. When the smelter starts its first furnace the crew should be increased to fifty miners. The tramway, 6300 feet long, connecting the mine with the Canadian Pacific railway, is running, and ore is being moved. The bins are complete, and ore is being crushed, while shipments of a car of siliceous ore are being received daily from the Quilp mine at Republic, Wash. The Quilp has a contract with the Sullivan for supplying all the siliceous ores required. Lime ore for flux is being received from the Hunter V mine, near Ymir. It is a low-grade silver product. The new Haberlin converter, being also tried experimentally by the American S. & R. Co. at Pueblo, Colo., is designed to reduce the sulphur and facilitate the free extraction of the zinc. The crude ore runs about 15% to 22% sulphur. It is crushed coarse and roasted in a revolving machine, to cut down the sulphur charge to 8%. Then it is still further converted in the Haberlin plant by a hot blast, which heats the ore almost to fusion and cuts down the sulphur charge to 4%. The ore, instead of being reduced to fine granules, as is done in most roasters, is left in good sized pieces much like coke, and the removal of the sulphur leaves air passages all through its texture. It is fed into the furnace without the expense of briquetting. In the smelter furnace fusion is secured with twice the speed of the old-time methods, since the blast is swept through the porous ore. There are only two products from the smelter—the silver-lead bullion and the iron-zinc-sulphide slag. The third product—a sort of middlings, made from slag mixed with lead—which is produced in smelting practice under ordinary conditions is avoided.

### BRITISH GUIANA.

During 1904 British Guiana exported 90,102 ozs. 13 dwts. 10 grs. gold, valued at \$1,599,042.95, and 11,045½ carats in diamonds, valued at \$85,947.22.

### CANADA.

#### Alberta.

The International Coal & Coke Co. elected: President, A. C. Flumerfelt; vice-president and treasurer, H. M. Galer; secretary, W. G. Graves. The company shows that Superintendent Reynolds took charge January 1, 1904, and during the year machinery was received, buildings erected, railway switches constructed, water works installed, and the whole plant was placed in a position for operation. A battery of 104 standard beehive coke ovens have been put in. The boiler and power house are built of masonry, with stone walls separating. This building is 82x78 feet and contains four 100 H. P. boilers, and foundations and connections are in for two boilers, heaters and pumps. In the power room two 250 kilowatt Westinghouse electric generators are directly connected with two 400 H. P. engines. A compressor for an air haulage system, compressing to a pressure of 1000 pounds, has been put in. The electric current generated runs a 150 H. P. motor, which drives an 11-foot Capell fan, with a capacity of 150,000 cubic feet of air per minute. An air locomotive does the hauling from inside the mine to the tippie. The tippie bins have a capacity for 2500 tons of coal and slack, and is so arranged that the coal and slack drop into different bins. As the mine cars of coal approach the tippie they run over a weigh scale, and from there onto a self-dumping cage, which is raised to the top of the tippie by a 100 H. P. hoist. When these cages arrive at the top they dump the coal onto screens, the slack goes through into slack bins and the coal onto two picking tables, 5 feet wide and 40 feet long, run by a 25 H. P. motor, and as the coal passes over these picking tables all rock and refuse matter is picked off. The coal runs out of the tippie bins by gravity, through a chute into cars. The slack for the ovens is taken from the slack bins and conveyed by electric carriages to the coke ovens, where it is charged. At the slope a 50 H. P. boiler and a 5x7 hoist has been used for development work, but will be replaced by a larger hoist. In 1904, 51,000 tons of coal and coke were shipped.

## Vancouver Island.

(Special Correspondence).—The January returns of the Tyee Copper Co. show that the smelter at Ladysmith ran twenty-three days and smelted 5065 tons of Tyee ore, giving a return after deduction of freight and refining charges of \$68,662. The reduction plant is 20 miles from the mine at Duncans. The ore is received from the railroad at the receiving bins, having a capacity of 1600 tons, from which the ore is run into cars running on tram track on movable bridges with wheels. The ore is then heap roasted in piles 50 feet long by 24 feet wide and 7 feet high, each containing 225 tons of ore, using six cords of wood to the pile. It takes four weeks to burn the pile to 5% sulphur.

Duncans, Feb. 19.

## Yukon Territory.

The Yukon Territory, which prior to 1898 formed a part of the Northwest Territory, has an area of 196,976 square miles, 196,327 being land and 649 water. The population is estimated at 12,000, of whom 7200 are Americans. It is purely a mineral country, and has produced since 1885, when the output of gold was first recorded, to the end of 1903, \$97,063,500 in gold. During the same years the gold mined in the rest of Canada was as follows: Saskatchewan district, \$292,946; Province of Ontario, \$2,086,393; Province of Quebec, \$103,940; Province of British Columbia, \$40,545,398; Nova Scotia, \$9,318,984; a total of \$52,347,661. The production of Yukon Territory thus exceeded that of the rest of Canada, since 1885, by \$44,715,839. In the most prosperous years for the Yukon, those from 1898 to the present, the production of gold has been as follows: 1898, \$10,000,000; 1899, \$16,000,000; 1900, \$22,275,000; 1901, \$18,000,000; 1902, \$14,500,000; 1903, \$12,250,000; a total in six years of \$93,025,000. Dawson, the capital of the Yukon Territory and the residential and commercial center of what is commonly known as the Klondike, has a population of 3500 persons of various nationalities, the Americans, with 2450, forming 70% of the total. The city is easily reached during the season of navigation (from about May 15 to October 10) in seven to nine days from Seattle, Wash., or Vancouver, British Columbia, by three lines of steamers to Skagway, Alaska (three to four days), where connection is made by rail to White Horse (one day), the head of navigation on the Yukon river. From White Horse the White Pass Line runs comfortable boats to Dawson in from three to four days. This company operates, between White Horse and Dawson, twelve vessels and five barges, with a capacity of 3500 tons. During the season of 1904 it handled 22,447 tons of freight and carried 4932 passengers. Passenger rates from Seattle to Dawson are \$80 first class and \$65 second class. Freight rates from Seattle to Dawson by the carload are \$3 to \$4.25 per 100 pounds. Commodity rates from the Pacific coast points during midsummer are \$2.37 per 100 pounds. From Dawson the rates to Eagle, Chena or Fairbanks, and Fort Gihon, Alaska, are, per ton, \$10, \$70 and \$40, respectively. The White Pass rail division between Skagway and White Horse, 111 miles, operates daily passenger and freight service, with a capacity of at least 5000 tons a day. There is a second though much longer route, taking twenty-three days from Seattle to Dawson by way of St. Michael, Alaska. Two steamboat lines run on the lower Yukon river between St. Michael and Dawson—the Northern Commercial Co. and the North American Transportation & Trading Co. The former operates twenty-two steamers and barges, with a total net tonnage of 7851 tons, and the latter nine steamers and barges, with a total gross tonnage of 6083 tons. The passenger rates by these two lines is \$125 from Seattle to Dawson, and the average rate per ton on freight is \$60. Besides the boats of the above companies there are eleven independent steamers, American and Canadian, plying between White Horse and Dawson and points in Alaska on the Yukon river. Some of these have comfortable accommodations for passengers.

At Dawson the Canadian Klondike M. Co. of Detroit will install a 400-kilowatt turbo-generator to be driven by a 600 H. P. Westinghouse-Parsons steam turbine to operate dredge boats being built by the Marion Steam Shovel Co. of Marion, Ohio. On these boats will be installed induction motors varying in size from 7½ to 100 H. P. The power house will be at Dawson City, and the dredges will operate on the Yukon river and its tributaries. Lines for transmitting power will be strung from the station to the boats, wherever they may be working.

## CENTRAL AFRICA.

J. R. Robinson, mining engineer of the British Central Africa, Ltd., has selected four 506 square mile blocks of country, 2000 reef claims and two extensive coal areas in the B. C. A. Protectorate; also a large number of gold reef claims in the territory of the Companhia D. A. Zambesia, near the northern Portuguese boundary. Within these areas important finds have been made of lodes containing gold, argentiferous galena, pyromorphite, cerussite and copper ores, also graphite, iron ore, limestone and transparent mica, in plates from 12 to 16 inches, in the North Nyassa district, adjacent to the Anglo-German frontier. From the discoveries recently made, it would appear that the vast territories north of the Zambesi offer immense mining possibilities on the introduction of the necessary capital. The recruiting of labor in this district for the Transvaal mines has proved successful. All the natives recruited have volunteered their services without the faintest hesitation. The Government officials do not render the slightest assistance in the recruiting of natives under their jurisdiction. The natives who have returned from the mines speak well of the way that they are treated and paid by their employers in the Transvaal. There are thousands of natives living near Lake Nyassa who are unable to procure employment from the sparse European population in the northern provinces; consequently, 15,000 go to South Africa annually from Angoniland, Atongaland and the Apeya country. The vast and densely populated region lying between lakes Mweru, Bangweulu, Tanganyika and Nyassaland has never been exploited for labor, and an inexhaustible supply could be drawn from that quarter, providing permission was granted by the Rhodesian authorities.

## KOREA.

The U. S. Consul at Seoul reports that the largest American enterprise in Korea at the present time is the Oriental Consolidated M. Co., operating on a concession 500 miles square in northwest Korea. It employs seventy white men and several thousand Asiatics, and operates five mills on its concession, with a total of 200 stamps. In 1903 it mined and milled 203,567 tons of ore, valued at \$1,478,956, and had in sight on December 31 ore to the value of over \$6,000,000. It has now about completed a large dam for a reservoir to furnish water power for an electric plant, by which its mills will be run. The plant is to cost completed \$200,000. In this connection the following figures, giving the export of gold from Korea to foreign countries for the past ten years, is of interest: 1894, \$465,169; 1895, \$473,758; 1896, \$692,425; 1897, \$1,012,971; 1898, \$1,183,111; 1899, \$1,460,824; 1900, \$1,809,258; 1901, \$2,486,688; 1902, \$2,521,925, and 1903, \$2,717,285. These figures do not include a considerable quantity of gold mined by natives but not exported through the treaty ports. Other foreign mining concessions are operated in Korea by British, German and Japanese companies, but have thus far proved by no means so successful as that of the American company. Considerable deposits of gold have recently been discovered a short distance from the city of Pyongyang, in the northwest, and it is reported that 25,000 Koreans are now in that region engaged in placer mining. It is doubtful, however, if the deposits in that locality will hold out very long, and the returns to each individual miner can not be very great. In 1903 mining supplies to the value of \$212,964 were imported.

## MEXICO.

The Dynamite Concession amendment states that on March 1, 1905, or when the National Dynamite & Explosive Co. is in better condition to supply the Mexican markets with dynamite, a duty of \$210 per metric ton (1000 kilos) will be put on foreign dynamite—this is 21 cents a kilo. While the concession is in force the duty shall not be reduced below \$30 per ton, the present rate on imported powder. This is the duty, or rather tax, that the native dynamite factory has to pay the Government on all dynamite manufactured. Common black powder, fuse and caps, which are not made in this country, are exempt of these duties. If the duty of \$210 should not be put on at the time stated above, or Congress sees fit to reduce same after it has gone into effect, the Government shall make good the loss sustained by the National Dynamite & Explosives Co. The company may make any grade of dynamite that is required, but must keep in stock for consumers dynamite containing 30%, 40%, 50%, 60% and 75% nitroglycerine or other explosive of the same character that has been appropriated by the Government. The prices of native dynamite are fixed by the Government, and a discount of 5% is allowed with the understanding that all cases contain 22.68 kilos, or about 50 pounds. The prices fixed by the Government vary according to location (supposed to be based on the freight rates from the works to the different points) and can not be increased except in special cases and by the Secretary of the Fomento. Until there is a means of transportation to the Pacific coast, dynamite can be imported into that section with a duty that would make the dynamite cost the same as if it were shipped from the native factory. The following are the prices in cents sold per pound for some of the principal mining camps:

	30%.	40%.	50%.	60%.	75%.
Parral.....	15.58	16.85	18.13	19.40	21.95
Aguascalientes.....	15.35	16.62	17.89	19.17	21.72
Chihuahua.....	14.71	15.98	17.25	18.53	21.08
Guadalajara.....	15.35	16.62	17.89	19.17	21.72
Mapimi.....	15.29	16.56	17.84	19.11	21.68
Oaxaca.....	16.91	18.18	19.46	20.73	23.28
Pachuca.....	15.35	16.62	17.89	19.17	21.72

On the Pacific coast, until such time as means of transportation are provided, permission is given to import dynamite through the custom houses paying the amount which would correspond to the same if manufactured by the company.

## Chihuahua.

H. C. Wilmet of New York will develop the San Martin claim in Santa Barbara belonging to D. P. Ellissague. —W. M. Brodie, Box 219, Chihuahua, is to secure data regarding the building of a smelter at Chihuahua.

## Guajuato.

It is reported that D. V. A. Williams of the City of Mexico has interested people from Detroit, Mich., in building a 100-ton custom mill and cyanide plant at Marfil to treat the low grade ores of the district.

## Jalisco.

G. E. Purnell, president of the Guadalajara Banking Co., at Guadalajara, is preparing to reopen and work the Boca Ancha mine in the Parnase district. The mine is being equipped with hoiler, pump and hoist, and plans and estimates are being prepared for the erection of a plant.

## Sonora.

(Special Correspondence).—A party of mining experts from New York, including R. T. Hill, formerly with the U. S. Geological Survey, have been inspecting the Greene properties at Cananea. The Arizpe M. Co. report having struck a vein of silver in their Alacran mine which assays 560 ounces. This mine is 35 miles south of Cananea. —The Swansea M. Co., at Cananea, are pushing development work and are constructing an additional tunnel 500 feet long. —F. L. Proctor and McMillan Bros. of Cananea, owners of the Dos Naciones claims adjoining the Cobre Grande, have found rich silver and copper ore running \$40 per ton. —El Tigre mine has put in six new Nissen stamps. They are the first of the kind to be used in this section and are giving satisfaction. —High-grade ore is reported to have been struck in the Copper Belt mine, recently purchased by the Phelps-Dodge Co. —Surveying parties are locating a route for the proposed line by which W. C. Greene will transmit electrical power from a plant to be built on the Yaqui river, 80 miles from Cananea. The plant will be run by water power, and will be used to operate the smelter at Cananea and various saw mills in the Sierra Madre district. —The Calumet & Sonora have defini-

tely fixed their boundary lines, which were in dispute, and development work will now be pushed rapidly. Cananea, Feb. 19.

The Keystone Exploration Co. has been formed to work sixteen claims near Nacozari. R. C. Miller of Boston, Mass., is president; S. M. Langworthy of Cedar Rapids, Iowa, vice-president; H. B. Miller of Boston, Mass., secretary and treasurer; R. O. Dillon of Nacozari, Mexico, superintendent. —G. Woodward has sold the San Juan de Bautista mine, near Moctezuma, to the Beneficence M. & M. Co. for nearly \$2,000,000. The company is a part of the Washington-London Guarantee Investment Co. It is claimed work will be commenced on the property as soon as possible, and there is talk of a reduction plant. The ores are gold and the mine is an antiqua.

## Personal.

H. HARKER is superintendent Gold Dust mine at Leesburg, Idaho.

ALGERNON DEL MAR is at Silver Peak, Esmeralda county, Nev.

E. O. DANE is assistant engineer Mountain Copper Co., Martinez, Cal.

J. CLECHORN is superintendent Utah-Goldfield M. Co. at Goldfield, Nev.

CHAS. RUTER is examining mines near Kingman, Mohave county, Ariz.

F. BEEDLE is visiting in Deadwood, S. D., on a vacation from West Africa.

F. C. FENNER is managing director Wolverine & Arizona M. Co. at Bisbee, Ariz.

S. BLIGHT has returned to Grass Valley, Cal., from La Cananea, Sonora, Mexico.

A. C. GALLUPE is superintendent Mineral Hill mine, near Placerville, Boise county, Idaho.

E. W. JONES is superintendent Cerro Azul M. Co.'s properties near Imuris, Sonora, Mexico.

N. C. BONNEVIE of Denver, Colo., has returned there from Pittsburg, Pa., and other Eastern cities.

W. H. LEFFINGWELL, a mining engineer of Salvador, Central America, is in Berkeley, Cal., on a visit.

W. R. RUST, general manager Tacoma smelter has returned to Tacoma, Wash., from Los Angeles, Cal.

B. MATTIOTTI has charge of the Japan mine in Savage basin, near Telluride, San Miguel county, Colo.

S. CHOATE is superintendent of the Gold Bullion M. & M. Co. working on Monumental creek, near Roosevelt, Idaho.

F. A. HARTMAN, president of La Dura M. Co., has returned to Los Angeles, Cal., from La Dura, Sonora, Mexico.

E. A. H. HAYS has resigned as manager of the mines and smelter at Maconi, Mexico, and is at Fuerte, Sinaloa, Mexico.

M. McDONALD is general manager Goldreed M. Co., and R. Wardle, superintendent Goldreed, Esmeralda county, Nev.

M. D. PICKEL is superintendent of mines on Newman hill, near Rico, Dolores county, Colo., worked by the San Juan Ore Co.

F. ADAMS, manager Economic mill at Victor, Colo., has resigned and will go to Big Horn, Idaho. He will be succeeded by F. Kreutzer.

W. H. GODFREY, superintendent St. Paul & Montana M. Co., has been in the East on business connected with mines on Wisconsin creek, near Sheridan, Mont.

AL. ROBERTS has resigned as assistant superintendent of the Combination M. Co. at Goldfield, Nev., to become superintendent St. Ives M. Co. at Goldfield, Nev.

A. E. DRUCKER is superintendent of a gold and copper property in the Moctezuma district, Sonora, Mexico. D. G. Putnam of Los Angeles, Cal., is at the same property.

R. H. LEADLEY, for the past three years with the Torreon smelter in Coahuila, Mexico, is now with the Yaqui S. & R. Co. at San Antonio de la Huerta, Sonora, Mexico.

H. T. TRIPP has been appointed superintendent of the Alaska Nowell G. M. Co., with J. McBride as assistant superintendent at Nowell City, 75 miles northwest of Juneau, Alaska.

## Obituary.

J. M. TONG, a mining man of Clear Creek and Summit counties, Colo., died in Georgetown, Colo., February 9, after an illness of a week.

P. W. KEYES, a pioneer mining man of the Comstock, was found dead at the bottom of the dump of the Mammoth mine, in Six Mile canyon, near Virginia City, on Feb. 16. Keyes had been at work in the mine and was riding an ore car to the dump, when he lost control of it and rolled over the precipice to his death. Keyes died a comparatively poor man, though at one time the late J. W. Mackay offered \$75,000 for his interests in one mine near Virginia City.

WM. SKINNER, a well-known mining man, was killed on Feb. 3 by falling from the gallow's frame of the San Patricio mine, near Parral, Mexico, to the bottom of the 150-foot shaft. His body struck a car at the top of the

shaft. He was born in Scotland in 1853 and has been in Mexico twelve years. He had charge of the mines of the Montezuma Lead Co. of Santa Barbara three years ago, and since has been in Parral.

## Books Received.

Electrical engineers testing direct-current machines and students of electricity at technical schools will welcome "The Testing of Continuous Current Machines," by Chas. Kinzbrunner, as a lucid guide for their work. The subject of instruments and apparatus is clearly presented, both in text and in illustrations; minute directions are given for the measurement of resistance, temperature, insulation, speed, magnetism, efficiency and losses; the subject of characteristics is well presented, and the appendix gives a number of typical test sheets that many practicing electricians could well follow. The practical testing and care of machines is given more space than is ordinarily found in such text books. Besides the detail and exactness of direction, the main recommendation to the book is that it not only tells what to do, but also why you do it. It is published by John Wiley & Sons, 43 East 19th St., New York City, for \$2, and will be sent postpaid by the MINING AND SCIENTIFIC PRESS upon receipt of the price.

"Zinc and Lead Deposits of Northwestern Illinois," by H. F. Bain, Bulletin No. 246 of the United States Geological Survey. It gives a good description of the present condition of zinc and lead mining in this region and forms a valuable contribution to the literature on economic geology. It states that, while zinc and lead minerals are found in southern Illinois with fluorspar, yet the commercial deposits are confined to the northwestern district, Jo Daviess county, near Galena, forming a portion only of the upper Mississippi zinc and lead field, which lies mainly in Wisconsin, but includes parts of Illinois and Iowa. The region is one of unmetamorphosed, little-disturbed, sedimentary rocks of Paleozoic age, and there are no igneous rocks in or near it. In this it stands in sharp contrast with most other districts in which sulphide ores are important. Within the Illinois district only Ordovician and Silurian beds occur. The ore is found as galena and spalerite in "crevices" or gash veins in the dolomite, shales and sandstones.

The progress that has been made in the application of electricity to metallurgy is shown by comparing the second English edition of "Electric Smelting and Refining," translated by W. G. McMillan from W. Borchers' German work with the first edition, published in 1897. According to the latest edition, over thirty elements are now commercially extracted by means of the electric current, either in the electric furnace or electrolytically. The book is really a short treatise on metallurgy, for it gives a brief account of all the important methods of extracting the metals that are also obtained by the electric current. Like most technical books, the subject matter presented has been somewhat antiquated by the current technical press, and while it gives a fair survey of the field up to the opening of the present century, yet it omits a number of interesting accounts of the more recent applications of electricity. It should be read by all interested in this branch, as it will probably save much unavailing research along lines already tried but found unsuccessful; but it should be followed by a study of the recent technical publications. Considerable space is devoted to unsuccessful methods, possibly in the hope of showing others where mistakes have been made. Probably trade secretiveness has prevented the publication of many recent developments—for instance, the production of nitrogen compounds from the atmosphere—to which no reference is made. The chapter on the electro-metallurgy of copper is good. It is published by Chas. Griffin & Co., Exeter St., Strand, London, England, and will be sent postpaid by the MINING AND SCIENTIFIC PRESS upon receipt of \$5.

## Commercial Paragraphs.

J. N. FLOOD, Denver, Colo., is visiting the works of the Gardner Electric Drill & Machinery Co., Cleveland, Ohio.

E. C. MEANS is with the Westinghouse Electric & Mfg. Co. in their Denver, Colo., office at 429 Seventeenth street.

T. H. PROSKE, 1734 Fifteenth street, Denver, Colo., reports the sale of a Little Giant drill sharpener to the Clover Leaf G. M. Co., Roubalx, S. D., and one to the Silver Lake mines, Silverton, Colo.

THE S. H. SUPPLY CO., Denver, Colo., are shipping machinery for a 20-stamp mill complete, with power, to Oregon; a carload of pumping machinery to Parral, Mexico, and a complete 50-ton concentrating plant to the Homelit M. Co. at Silverton, Colorado.

CARY & FIELDING, 1711 Tremont street, Denver, Colo., agents for Rand Drill Co. and the Power & Mining Machinery Co., have received orders for 4 Rand compressors for use in Colorado; one to go to South Dakota and 30 Rand drills for shipment to different parts of the country, also one cyanide plant for South Dakota, 3 Pierce amalgamators and one carload of ore cars for Cripple Creek, Colo.

F. W. THOMPSON, manufacturer of assayers' balances, 1717 Arapahoe street, Denver, Colo., reports the following recent sales of his patent multiple rider carrier for use on assayers' balances: Pueblo Plant, American S. & R. Co., Pueblo, Colo., 2; Eagle Ore Sampling Co., El Paso Con. G. M. Co., Mary McKinney M. Co., J. I. Brown, Cripple Creek, Colo., 1 each; E. E. Burlingame & Co., Denver, Colo., 1; Colorado School of Mines,

Golden, Colo., 1; Minnesota School of Mines, Minneapolis, Minn., 4.

THE Los Angeles-Pacific Railroad Co. will increase the capacity of their central power house at Vineyard, Cal., and install an additional substation in Los Angeles, Cal. The new electrical equipment has been contracted for with the Crocker-Wheeler Co. through its Pacific coast managers, the Abner Doble Co. of San Francisco, Cal. The contract comprises one 1200 K.W., three-phase, 50-cycle, 2300-volt, engine-type generator with a speed of 125 revolutions per minute; one 300 K.W. motor-generator set; one 400 K.W. motor-generator set; three 400 K.W. transformers; three 160 K.W. transformers; three 120 K.W. transformers and a 60 K.W. engine-type exciter.

## Latest Market Reports.

SAN FRANCISCO, February 24, 1905.

### METALS.

SILVER.—Per oz., Troy: London, 28½d (standard ounce, 925 fine); New York, bar silver, 61c, refined (1000 fine); San Francisco, 61c; Mexican dollars, 51c, San Francisco; 47½c, New York.

COPPER.—New York: Standard, \$15.50; Lake, 1 to 3 casks, \$15.50@15.50; Electrolytic, 1 to 3 casks, \$15.50; Casting, 1 to 3 casks, \$15.25. San Francisco: \$16.00. Mill copper plates, \$17.00; bars, 18½@24c. London: £68 6s 3d spot per ton.

The total visible supply of copper on hand February 1 was 15,733 tons, made up as follows: Chilean in Liverpool and Swansea, 4539 tons; American in Liverpool and Swansea, 2498 tons; sundry amounts in Liverpool and Swansea, London and Newcastle, Birmingham and France, 2621 tons; English in Liverpool and Swansea, 2200 tons; afloat from Chile and Australia, 3875 tons. There is no material change in the copper situation. The stock on hand shows a slight falling off from Jan. 1, 1905, and is lower than that of Dec. 1, 1904.

LEAD.—New York, \$4.60; Salt Lake City, \$3.50; St. Louis, \$4.12½; San Francisco, \$3.70, carload lots; 4½c 1000 lbs.; pipe 6½c, sheet 7, bar 5½c; pig, \$4.85. London: £12 10s 0d per long ton.

SPELTER.—New York, \$6.20; St. Louis, \$6.30; London, £24 7s 6d per ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

TIN.—New York, pig, \$28.75@29.00; San Francisco, ton lots, 30c; 500 lbs., 30½c; 200 lbs., 30½c; less, 31c; bar tin, \$3.2½@35c. London, £130 15s spot.

PLATINUM.—San Francisco, crude, \$18.50 per oz.; New York, ingot, \$19.50 per Troy oz. Platinum ware, 75@82c per gram.

QUICKSILVER.—New York, \$40.00@41.00, large lots; London, £7 12s 6d; San Francisco, local, \$38.00 per flask of 75 lbs.; Denver, \$45.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 31½c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 19.75c; San Francisco, Plumbers', 100-lb. lots, 16.50c.

ZINC.—Metallic, chemically pure, \$1.50; dust, \$1.10; 10c; sulphate, \$1.04c.

NICKEL.—New York, 55@60c per lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c per lb.; 100 lbs., 35c; 1000 lbs., 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

### STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$16.85@17.10; gray forge, \$16.85; San Francisco, bar, 3c per lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburg, \$23.00@27.00; open hearth billets, \$23.00@27.00; San Francisco, bar, 7c to 12c per lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, ½c per lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

LUMBER.—(Retail): Pine, ordinary sizes, \$24.00@5.00; extra sizes higher; redwood, \$28.00@30.00; lath, 4 cts., \$4.50@5.00; pickets, \$21.00; shingles, \$2.50 for No. 1 and \$2.25 for No. 2; shakes, \$13.50 for split and \$15.00 for sawed; rustic, \$28.00@35.00.

NAILS.—This week the basic prices are: Wire, \$2.77; Cut, \$3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, \$3.35; Cut, \$3.55; 10d to 16d, Wire, \$3.45; Cut, \$3.35; 8d, Wire, \$3.50; Cut, \$3.50; 6d and 7d, Wire, \$3.60; Cut, \$3.60; 4d and 5d, Wire, \$3.70; Cut, \$3.70; 3d, Wire, \$3.85; Cut, \$3.85; 2d, Wire, \$4.10; Cut, \$4.10. Special rates for carload lots.

LIME.—Santa Cruz, \$1.25 country, \$1.25 city per bbl.

CEMENT.—Imported, \$2.15@2.65 per bbl.; California, carload lots, \$2.10 f. o. b. at works; small lots, \$2.40 per bbl. in sacks, 4 sacks to bbl., 10c for each sack returned.

### GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 8½c; Hallett's, 8½c; San Francisco, 1000-lb. lots, 9c; 300@500-lb. 9½c; 100-lb. lots, 10½c.

COAL.—San Francisco, coast, yard prices: Wellington, \$8.00; Seattle, \$6.50; Coos Bay, \$5.50; Southfield, \$8.00. Cargo lot, Eastern and foreign: Wallend, \$7.50; Brymbo, \$7.50; Pennsylvania, hd., \$14.00; Scotch, \$8.00; Cumberland, \$13.00; Cannel, \$8.50; Welsh Anthracite, \$13.00; Rock Springs, \$8.50, long ton; Colorado Anthracite, \$14.00. Coke, \$10.50 per ton in bulk, \$13.00 in sacks; Sunnyside, \$8.50, long ton.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1\*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1\*\*, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11c. No. 2\*\*, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2.00 per keg.

CAPS.—3x, \$5.50@6 per 1000; 4x, \$6.50@7; 5x, \$8@8.50; Lion, \$9@9.50, in lots not less than 1000.

FUSE.—Triple tape, \$4.00 per 1000 feet; double tape, \$3.50; single tape, \$3.10; Hemp, \$2.75; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11c per set; 14 oz., 40s., 9½c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c per lb.; carloads, 23@23½c; in tins, 30c; soda ash, \$2.00 per 100 lbs.; hyposulphite of soda, 3@3½c per lb.; caustic soda, in drums, 3@3½c per lb.; Cal. s. soda, bbls., \$1.10@1.20 per 100 lbs.; sks., 90c@1.00; chloride of potash, 12@13c; nitrate of potash, 6½@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2½@2¾c; flour sulphur, French, 2½@—c; alum, \$2.00@2.25; California refined, 1½@2c; sulphide of iron, 8c per lb.; copper sulphate, 5½@5¾c; chloride of lime, spot, \$2.50@2.75; sulphuric acid, in carboys, 66% B, 1½@2c per lb.; nitric acid, carboys, 8c per lb.

OILS.—Linsed, boiled, bbl., 55c; cs., 60c; raw, bbl., 53c; cs., 58c; Lucol oil, boiled, bbl., 50c; cs., 55c; raw bbl., 48c; cs., 53c. Kerosene—Pearl, per gal., 19c; As, 19c; Star, 19c; Extra Star, 22c; Eocene, 21c; Elaine, 25c; Water White, in bulk, 12½c; Mineral Seal iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Minera; Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 16c; do., cs., 22½c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19½c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 63c; Bleached, do., 67c; Whale Oil, cs., 52@57c.

BORAX.—Concentrated, 6@7c per lb.; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

BONE ASH.—Extra No. 1, 5@6c per lb.; No. 1, 4@5c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c per lb.

MOLYBDENUM.—Best, \$2.75 per lb.

CHROMIUM.—90% and over, per lb., 80c.

PHOSPHORUS.—American, per lb., 70c.

SILVER.—Chloride, ½ oz., 90c@1.00; nitrate, 55c.

RED LEAD.—500 lbs. and over at one purchase, per lb., 7c; less than 500 lbs., 7½c.

MANGANESE.—Per lb., \$2.75.

MAGNESIUM.—Pure, N. Y., \$1.60.

SODIUM.—Metal, per lb., 50c.

BISMUTH.—Subnitrate, per lb., \$2.10.

URANIUM.—Oxide, per lb., \$3.50.

MERCURY.—Bichloride, per lb., 77c.

TUNGSTEN.—Best, per lb., \$1.25.

FIRE BRICK.—Domestic, carloads per 1000, f. o. b., factory square, \$25.00; soap and split, \$22.50; arch and wedge, \$27.50; skew back, \$30.00; circle, \$32.00.

FIRE CLAY.—Domestic, per ton 2000 lbs. in 125-lb. bags, double and dry ground, f. o. b., factory, \$8.50.

## Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

ELECTRICAL WATER HEATER.—No. 782,525. Feb. 14, 1905. M. H. Shoenberg, San Francisco, Cal. Assigned to Shoenberg Electric Appliance Co. of San Francisco, Cal., a corporation. This invention relates to an apparatus which is designed for continuously heating a flowing stream of water. It consists in the combination with an insulating heating chamber having supply and discharge passages at opposite ends of an electrical conductor located within said chamber and immersed in the liquid to be heated, and in the combination and arrangement of mechanism arranged and adapted to produce the desired result.

ELASTIC POWER TRANSMISSION DEVICE.—No. 782,560. Feb. 14, 1905. G. H. Harris, Stockton, Cal. This invention relates to a device for transmitting power and relieving the jar and shock due to intermittent or irregular impulses between the two parts. In the transmitting of power from apparatus which is subject to irregular impulses, such as gas engines, or where the power may be regular, but there are irregular strains upon the part to which the power is transmitted, it is desirable to relieve the parts of the sudden shock of these changes without injuriously affecting the actual transmission. This device is designed in its various parts and construction to bring about the desired result.

FLOATABLE CONCRETE PIER.—No. 782,557. Feb. 14, 1905. S. Hadlock of Port Hadlock and F. E. Brown of Port Townsend, Wash. This invention consists in the formation of a hollow structure of concrete which is adapted to be floated to position and in the combination of any number of such structures, which may be permanently fixed to form a wharf, pier, caisson, or other desired permanent structure. The object of the invention is to provide a hollow structure of concrete with suitable chambers, which structure may be built on ways, and after being built can be launched and floated to any point where it is to be used. If used for a wharf or equivalent structure, it may be sunk upon or into the material forming the bottom of the water, and any number of these independent structures may be aligned to form any desired wharf or structure, said caissons or boxes being afterward filled so as to become permanent.

## New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING FEBRUARY 14, 1905.

782,320.—UNDERREAMER—J. J. Brewster, San Francisco.  
782,438.—FURNACE—L. D. Rome, San Francisco.  
782,807.—DUMP CAR—C. Erickson, San Luis Obispo, Cal.  
782,334.—STOVE—C. M. Gunn, Sausalito, Cal.  
782,446.—FORM FOR CEMENT WORK—C. Gustafson, Oakland, Cal.  
782,557.—CONCRETE PIER—Hadlock & Brown, Port Hadlock, Wash.  
782,560.—POWER TRANSMISSION—G. H. Harris, Stockton, Cal.  
782,562.—TELEPHONE REGISTER—M. Hitt, Los Angeles, Cal.  
782,413.—TRASH CLEANING MACHINE—J. A. Hughes, Blaine, Wash.  
782,608.—BOILER CLEANER—F. W. Jackson, Needles, Cal.  
782,508.—CASING SPEAR—F. W. Jones, Santa Pau, Cal.  
782,666.—CLOTHES PIN—F. Kirkpatrick, Riddles, Or.  
782,611.—AMALGAMATOR—M. V. Lasswell, Oakland, Cal.  
782,451.—CUTTING SHEET METAL PLATES—J. Lee, San Francisco.  
782,674.—GEAR WHEELS—T. W. Lowe, Stockton, Cal.  
782,786.—TROLLEY POLE—J. F. Magney, Los Angeles, Cal.  
782,413.—TRASH CLEANING MACHINE—J. A. Hughes, Blaine, Wash.  
782,470.—BRIQUET MACHINE—R. Schor, San Francisco.  
782,525.—WATER HEATER—M. H. Shoenberg, San Francisco.  
782,433.—BUCKLE—G. Shoenberger, Long Beach, Cal.  
782,471.—ENGINE—Sterne & Davis, San Diego, Cal.  
782,425.—GOLD SEPARATOR—Stevenson & Heft, Grants Pass, Or.  
782,472.—FURNACE—Tucker & Grundell, San Francisco.  
782,513.—REAR ENGINE—E. Uren, Sacramento, Cal.  
782,477.—BOTTLE—O. Yates, Portland, Or.

## Old Times and the New.

There are some peculiarly noticeable features in the mining industry at this time which are worth more than passing notice. One of the most important of these noteworthy conditions is the successful operation of mines which were abandoned years ago, and which had long remained idle. Another feature is the finding of large and valuable ore bodies in unsuspected places in active districts, such as Cripple Creek and Leadville, Colo. The latter is merely the result of energetic prospecting and may be taken rather as an indication that the earlier operators were not so thorough in their development work as the miners of the present. In the Cripple Creek district most of the new finds have been made within a few feet of the surface, though strikes at depths between 800 and 1200 feet are not of uncommon occurrence there. It is more particularly the reopening of long abandoned and presumably worthless mines that is worth consideration, and it is from a study of the causes that make success possible to-day, which was not apparently obtainable in earlier years, that a lesson of profit may be learned by the operator of to-day. Many mines worked twenty-five to thirty years ago were improperly equipped—the science of metallurgy had not reached its present advanced stage. Mining methods were less carefully chosen, and caves in mines were of much more frequent occurrence than to-day under similar conditions. At that time machine drills were comparatively a new thing and but few were in use underground. The old Burleigh drill was the first drill to come largely into use, although several other drills of this type had been introduced previously. The name Burleigh is still indiscriminately applied by many miners to any make of machine drill. In many camps wages remain practically the same as twenty-five to thirty years ago, but mining supplies for most part are not only cheaper but better. Powder is an important item in the reduction of cost, for good powder to-day can be had for about one-third the cost of that time. Steel is better and cheaper and lights are generally cheaper, but in mining the greatest reduction in cost has been made in the application of improved methods for most cases and special methods for particular cases. Some of the old-time ideas have never been improved upon and seem unlikely to be, but in others there has been a vast change for the better. In some of the great mines which have been worked steadily for a quarter of a century or more the mining methods have been changed from time to time when it has been found that an improve-

Big Indian Mine and Mill, Near Helena, Mont. (See Page 134.)

ment could be made, until the methods of to-day are wholly unlike those at first employed. The Homestake mines, in South Dakota, furnish a striking example of this truth. In newly-opened old mines the modern ideas have usually been applied with good effect. In these cases it has not been a process of evolution from one stage to the next, but a radical change from antiquated methods, recognized as unsuited to the securing of the best results, to the most modern application of improved ideas. This, coupled with cheapened cost of supplies, power and usually of transportation, also, has made at once a paying proposition of one which never possessed the elements of profitable operation, or had ceased to possess them under the old regime. In almost every important old district of the West examples of the results obtained from this change of conditions and application of improved methods are seen. Mines which a few years ago were abandoned and classed as worthless, are to-day in operation and are proving profitable, and it has not always been a lack of proper management that has made this change for the better. Occasionally is seen a monument of folly, either in an elaborately equipped mine, with nothing to justify such equipment, or a mine possessing the elements of success which has

been managed by some one having neither practical mining experience nor business sagacity, but in most cases the management of earlier days was good, but unequal to the odds against success. The most careful management cannot make a \$3 mine pay where the actual cost is \$4. If in after years the cost is reduced to \$2, then the \$3 mine becomes a paying proposition. There are many mines working to-day which barely pay expenses, and yet which constantly offer hope of an improvement. In such mines the improvement sought must usually be found in strict, but not parsimonious, economy, and in the endeavor to extract a higher percentage of values without increasing cost, and by lessening it, if possible. In this regard the ratio of possible output to the hoisting and milling plant is of importance. It is generally more economical to operate a large than a small plant, but the size of the plant should be determined with careful consideration.

## Railroads in West Africa.

Among the most difficult engineering accomplishments of the day is the construction of railroads through the jungles of West Africa. These fore-runners, of what is hoped will be the civilization of that portion of the world, are constructed under the extreme of difficulties, through a virgin forest reeking with malaria, and where white men can only remain a short time without becoming victims of the climate. The labor is almost wholly unskilled and the difficulties of the engineering corps are ten fold those found in almost any other part of the world. These conditions render railway construction very expensive. Still, there are great latent resources in the country, including gold deposits. These have been worked in a fashion determined by the existing conditions. While it is thought that the construction of railways in that region will bring about the development of the country more rapidly, and make it possible to equip and operate mines and other industries at less expense than in the past, it is not believed that white men will ever find the climate endurable, and frequent changes in management and staff must always take place. The native workmen, however, may in time be educated to a point where they will be of far greater service than now. Notwithstanding all the drawbacks of remoteness from civilization, and fatalities due to climate, over 500 miles of railroad have been built in West Africa, through a wilderness in which there was neither highway nor trail. Rain, if not incessant, is of frequent occurrence, and much opposition from natives was encountered.

THE wise mine manager is always ready to buy or install any mechanical or other device which will result in economy of operation. Some men who have the reputation of being even niggardly in their management are the first to take up any new invention or tool which is offered. An investigation will show that this tool, device or process is making a saving of money or time for that manager, and it is a compliment to his business sagacity and not a proof of his parsimonious administration. A device which will save even \$1 per day pays interest on an investment of about \$5000. The wisest mine management is he who accomplishes the greatest results at least expense of time and money without friction between employer and employee.

THE Mountain Copper Company of Shasta county, Cal., is endeavoring to find a means of economizing in the cost of copper production, and, probably, at the same time making plans which will prevent a repetition of the difficulties in which they became involved through the long-continued strike of its smelter employees. It has taken the first important step in the direction indicated by making preparations to establish a refinery at Bull's Head Point, near Martinez, in Contra Costa county, Cal. It is now stated to be the intention of the company to continue the operation of the smelters at Keswick, in Shasta county, but the making of high-grade matte and copper bars at that place will be discontinued, and, instead, low-grade matte will be the product, which will be shipped to their refinery on tide water, which is now under construction, for refining. By this means the cost of copper production will be reduced. The matte produced at Keswick will prob-

ably contain 20% to 25% copper and sufficient sulphur to make a valuable by-product in acid manufacture at its tide water plant. A scheme somewhat similar has been adopted by the Broken Hill mine of New South Wales, Australia, which is situated far inland, but which has found it advisable to place the acid plant on a seaport. The smelting operations of the Mountain Copper Company, as conducted at Keswick, is almost straight pyritic smelting, very little coke being added to the charge.

## Character in Mining.

The White Knob Copper Company's mines near Mackay, Idaho, and the Majestic Company's copper mines near Marysville, Utah, offer excellent examples of the unfortunate result of the premature equipment of mining properties. On each of these groups large amounts of money have been expended, mostly in equipment, though a considerable sum has also been spent in development, particularly in the former; but at no time in their history, apparently, have either of these properties justified the extensive metallurgical equipment found on them. A few days since the White Knob property was sold at sheriff's sale. The Majestic property has fallen into new and, it is to be hoped, better hands, and its management will probably henceforth be along more conservative lines. These mines may have great intrinsic merit; but, if so, their management has not been such as to demonstrate it. Mining has been reduced to a practical science, and, in view of the broad knowledge of all that now appertains to mining, and where no unusual difficulties in a metallurgical way present themselves, there seems small excuse for the expensive and elaborate equipment of a mine with reduction works, only to find that there is insufficient ore to supply the plant. Apropos are the words of Governor Brady of Alaska in his recent annual report, in which he condemns in unmeasured terms the policy of deceit which has apparently dominated some large recent investments in Alaska. There are instances where great sums of money have been expended fruitlessly, unless additional large sums be invested. The great mines on Douglas Island, Alaska, in a measure represent a condition of this kind. In their earlier history their milling plants were comparatively small. As mining expense increased, the profit fell off and the character of the ore changed somewhat also, and not to the advantage of the company, either. It was suggested that the mill be increased to 240 stamps. At that time the largest number of stamps under one roof was the 120-stamp mills of the Homestake Company. The directors were somewhat skeptical of the favorable outcome of such a venture; but, being assured by engineers that the scheme was entirely feasible and would result in increased profit, the investment was made and great success resulted. Since then the Alaska Company has built larger mills. In this instance the mine fully justified the elaborate outlay and it had become evident that little or no further profit could be derived from the operation if the milling facilities were not largely increased, as the handling of a much larger tonnage would reduce the cost of both mining and milling and also decrease the charge per ton for those important items which fall under the comprehensive title of general expense. A proposition of this kind is one of the most perfect illustrations of legitimate mining, while the same can not be said of those concerns which build extravagantly first and search for a mine afterward.

THE recent transfer of the control of the forest reserves from the Department of the Interior to the Department of Agriculture is important, but the privileges of miners are not apparently abridged by this change. Elsewhere herein is a letter from the Secretary of Agriculture to the chief forester, in which the matter is discussed at length. In this letter the Secretary says that the rights of way for the construction and maintenance of dams, reservoirs, water plants, ditches, flumes, etc., within and across forest reserves are granted to citizens of the United States for municipal or mining purposes, and for the purposes of milling and reduction of ores. The object of the transfer of the Forestry Bureau from the Department of the Interior to the Department of Agriculture is that the forests may be better protected from destruction and waste. As the

country becomes more populous the forests become more valuable, and there is a constantly increasing tendency to encroach upon and destroy them. It is a well known fact that in regions once covered with forests, where the water supply has been abundant, that upon the denudation of the forest the country became a semi-desert in consequence. Water is invaluable to the miner, and miners should unite to preserve as far as possible the existing forests. Despite the efforts heretofore made, there has been a vast destruction and waste of forest trees in the mountain regions of the West, and these regions are usually incidentally mining regions, or the mining regions beyond the forests depend upon the rainfall and its preservation within the forest region. With the disappearance of the forest the water supply grows short and eventually ceases almost entirely, for the "run off" is so rapid that few perennial springs are formed.

## Paying for the Privilege of Working.

Occasionally from various quarters comes the report of the demoralization of mine crews by the extortion of bosses and foremen, who, by various means, obtain money from workmen which is never repaid. In some instances bribery to secure a position is the demoralizing feature; in others, the men must patronize certain establishments about town in order to hold their jobs; in still others, on pay day the boss, or foreman, solicits a loan from certain of the men, and this loan is never repaid, nor, in many instances, is it expected. It is the foreign element among miners who are the usual victims of such practices and who submit either willingly, or sullenly hold their peace waiting for an opportunity to play even. That the best results are obtainable where such practices are in vogue is impossible. A man, having secured his position by bribe, whether it be a loan, or agreement to patronize certain trades people in the town, feels secure, and he shirks his work at the expense of the company. Miners of intelligence will not submit to extortion of this sort, and prefer to hold their places by merit alone, or to lose them if required to pay for the privilege of earning an honest livelihood. There are well authenticated instances where shift bosses have obtained thousands of dollars from the men under their direction. The management of mines should see to it that no such practices are carried on in the properties under them. It is only a few days since a number of Slavonian laborers united in a legal action to compel a former shift boss of an Alaska mine to refund money extorted from them in various ways. Of course these pernicious practices are never carried on openly, and the management remained in ignorance of the existing condition. It is thought the exposure will have a purifying effect on the mine and town as well, for men who will submit to this sort of thing do not make good or desirable citizens.

## A Successful Effort.

At the annual meeting of the California Miners' Association, held in San Francisco, Cal., last December, the debris problem was discussed at length by Prof. S. B. Christy of the University of California, who gave much detailed information on debris in rivers in general and the methods adopted for control. In accordance with the suggestion of Prof. Christy, the committee on resolutions prepared a memorial to President Roosevelt setting forth the present condition of the Sacramento and San Joaquin rivers in California, and their relation to the mining industry of that State, and soliciting his personal aid in finding a solution to the problem of caring for the debris in a manner which would permit the continuation of the mining industry without injury to other interests. The suggestion was also made that the matter be referred to the Director of the United States Geological Survey, and, in his study of the storage of flood waters and the reclamation of waste lands, give the debris problem his official attention. E. H. Benjamini, president of the California State Miners' Association, is just in receipt of information that the matter has been given consideration by President Roosevelt and that the debris problem of California will thus be taken up by the Geological Survey, and all that science and engineering experience can suggest will be done to find a satisfactory solution of the difficulty.

## CONCENTRATES.

WIRE CLOTH screens with rectangular openings have a slightly greater capacity and do not choke as readily as screens having square openings.

THE best mine timbers for general use are those which will resist the greatest thrust. Often mine timbers are also required to sustain severe bending strains.

TAMPING over dynamite is essential in securing the best results with the least powder. The explosive force of free dynamite is exerted equally in all directions.

STRAIN is a change, either of volume or form, in the relative position of the particles of a body; it is distortion when the form changes; dilation when the volume changes.

A SLOTTED SCREEN is better for flinty ores with splintery fracture than needle-pinch or wire screens. Granular ore crushes to granules and will readily pass any kind of a screen when crushed fine enough.

CHALCOPYRITE is brass yellow, pyrite pale yellow and arsenopyrite silver white to grayish. It is often tarnished to dark gray. Chalcopryite is softer than pyrite and may be easily scratched with a knife. Pyrite can not be thus scratched.

THE depth to which a hoisting engine of given capacity will operate depends upon the weight of the load and the speed at which it is intended to run it. An engine of given capacity will hoist from much greater depth at slow than at fast speed.

GOLD may be free in an ore, but occur in such an extremely fine state of division as to be invisible to the eye. This kind of gold is adapted to cyanide treatment. Often attempts to amalgamate it fail, for the reason that the ore has to be crushed so fine to free the gold that there is a heavy loss in slimes.

It is not customary to "harden" the shanks of machine drill steel, for the reason that the frequent hard usage to which they are subjected, such as pounding with a wrench or hammer, when the drill becomes flitchered, is likely to result in breaking the drill. If desired, the shank may be tempered in the same manner as the bit, by plunging at a low red heat, but it is not advisable practice.

WHERE an ore is susceptible to treatment by more than one method the surrounding conditions—transportation costs, power, etc.—should determine which process under existing circumstances should be adopted. Where doubt exists tests should be made to decide which process or class of machinery is best adapted to the conditions and character of the ore.

THE capacities of rock crushers, as given in manufacturers' catalogues, are necessarily approximate, being usually based on a hard, friable rock, fed constantly and clearing itself quickly at the outlet. The H. P. required likewise varies—1 H. P. per twenty-four hours, crushing eleven to twelve tons to  $\frac{1}{4}$  inch, sixteen to nineteen tons to 2 inches, and eighteen to twenty-two tons to  $\frac{3}{4}$  inches.

ALL cylinders, receivers and pipes of an air compressor should be frequently cleaned of accumulating oil, deposited carbon and organic dust. The air intake should be located where an abundant supply of pure, cool air may be obtained. If these precautions are not taken there is danger of the production of carbon dioxide from the heated carbon deposits. This will suffocate and kill miners, if supplied to air drills.

THE gauge pressure, when pumping against a closed valve with a multi-stage turbine pump, to be equivalent to pumping any given capacity against any vertical lift, should be equal to the total head necessary to raise the desired amount of water. This depends upon the velocity with which the water leaves the pipe, and the length, diameter and coefficient of friction of the pipe, letting Q be the number of cubic feet pumped per second.

SWITCHBOARD PANELS for electric plants are made from white Italian marble, blue Vermont marble and slate free from flaws or conducting veins. Soapstone is used for other electrical purposes, but is too soft and weak for panels. A 10,000-volt testing box is used to test for conducting veins. They are made in standard widths and heights and vary from  $1\frac{1}{4}$  inch to  $2\frac{1}{2}$  inches in thickness, according to weight of apparatus.

THE spacing between the points of water distribution on a concentrating machine of the belt type is important, for the best work is impossible if the little streams of fresh water are either too close or too far apart, though the latter is worse than the former. The distance between the points must be determined by the length of side vibration of the belt. The proper distance in most machines of this class is about  $2\frac{1}{2}$  inches.

ZINC SHAVINGS in the precipitating boxes should be changed daily, those from the lower portion of the series being moved upward as the shavings from the head box are removed for treatment. To strengthen cyanide solutions for proper precipitation, a tank or barrel may be placed at the head of the series of precipitating boxes, and the strong solution added as required by allowing it to drip slowly as the gold-bearing solution passes into the boxes.

WHERE a dam is built in a stream and the work is well and carefully done, the owner is not liable for damages which may result should the dam break away. Negligence must be shown in order to make him liable. (Losee v. Buchanan, 51 N. Y. 476, 10 Am. Rep. 623.) Dams must be so constructed as to resist such floods as might be reasonably expected to occur. (Todd v. Cochell, 17 Cal. 97; Hoffman v. Tuolumne Water Co., 10 Cal. 413; Camboll v. Bear River & Auburn W. & M. Co., 35 Cal. 679.)

METALLIC IRON decomposes cyanide solutions and this tendency is increased in proportion to the surface exposures of the metal. For this reason it is desirable to keep the amount of iron particles resulting from crushing ores for cyanidation as low as possible. A mill which has a high stamp duty produces generally less iron particles per ton of ore from shoes, dies and mortar, than one of low capacity. Some ingenious magnetic arrangements have been devised to separate a large percentage of these iron particles from the pulp as it passes over the plates from the battery.

BORAX swells upon heating. It colors the blowpipe flame yellow. Colemanite, the principal borax mineral, is calcium borate. It crumbles when heated before the blowpipe and colors the flame green. Nearly all borates impart a green color to the flame. Colemanite is colorless or white, translucent to transparent, soft (a little harder than calcite, easily scratched by a knife). When nitrates are heated in a bulb tube with potassium bisulfate, red vapors of nitric oxide are given off. Sodium nitrate colors the blowpipe flame an intense yellow. Potassium nitrate colors the flame violet.

THE main shaft of the Silver Islet mine, located on a small island near the north shore of Lake Superior, was sunk in the center of the islet—a rock about 80 feet square which projected a few feet above the water. A coffer dam was built about the island, but it was swept away by the heavy storms. This was repeated several times until a dam was built which was able to resist the action of the waves. The shaft was sunk and the mine worked to a depth of about 500 feet, and, although lying wholly beneath the level of the lake, it was one of the driest mines in America. It is at present idle.

THE purpose of a compressed air receiver is to reduce the pulsations of the air from the compressor, to collect water and grease carried by the air in the pipes. The receiver is not intended as an air reservoir of power, though to a limited extent it may be employed for this purpose, as in the event of sudden stoppage of the compressor for any cause the air in the receiver may have sufficient volume and pressure to accomplish some work, such as hoisting a skip in a shaft that had already been started by the engines, which are run by compressed air. The extent to which the receiver may be used for this purpose depends upon the volume of air and its pressure. The principle is exemplified in the compressed air motors.

IN view of the numerous accidents resulting from defective fuses, it seems strange that the manufacturers are not required to guarantee the fuses sold by them. It is true that some of these accidents charged to defective fuses are really due to the improper use of the fuse itself by the miners, and in some cases it is kept for a long time in damp magazines or in the mine, which results in premature deterioration. The date of making fuses should be stamped upon the case containing it, and also upon the paper in which the coils are wrapped. At present it appears that the only measure to protect the lives of men using blasting fuse is for the miners themselves to test the fuse they are required to use.

THE idea of pulverizing an ore sample and mixing wet with black gunpowder, forming into a cone-shaped pile, drying and burning the cone is an old one and at one time, thirty years ago, was popular with prospectors. With some copper and silver ores there is undoubtedly sufficient heat developed to cause some of the metals present to be reduced to metallic condition. The mass was then pulverized in a mortar or on a rock, washed, and the metallic particles collected by panning. In this operation the iron oxide, which may be present in the ore, and metallic particles of iron from mortar and pestle also, are fused to globules of metallic malleable iron—and these globules the prospector usually mistakes for silver or some rare metal. This method of testing ores is no better than a guess, and the experienced prospector can guess the value of his ore as closely before as after this operation. Beyond panning the free gold in an ore, it is impossible to guess what the ore may be worth, and the only reliable method is the assay made by a competent assayer. That the "aluminum welding" process would be of any value in determining the value

of ore is extremely doubtful. By none of these methods (those of mixing dry pulp with a combustible substance and burning the mixture) can reliable information be obtained, for the reason that these methods at best are crude. The metallic contents of the ore are not collected in a single globule, as in assaying, and the whole effort is a waste of time.

"THE rhombohedral" theory of jointing planes in rock was one advanced by Louis Janin, Sr., during the progress of a mining suit at Grass Valley, Cal., in which it was contended by Mr. Janin that the country rock in which the vein in dispute occurred was divided into rhombohedral blocks, by means of an auxiliary system of joints, and that this fracturing of the country rock had resulted in a certain amount of movement along these jointing planes and the formation of certain small veins called by the miners "droppers," which formed a connection between two portions of the same vein, but which had formed at one portion a sort of overlap. The section of the mine in which this occurred was a region of some disturbance. An upper vein "feathered" out, and several feet below in the footwall, what was apparently a second vein, which continued on the downward course of the vein above. These two veins were connected by these small veins running into the footwall from the vein above. It was found, however, that at a distance from this region of disturbance that the split and overlap of the main vein disappeared, and that there was simply a single vein which at one place developed this unusual peculiarity.

WHAT is known as "Schmidt's law of faults" depends for its success upon the rule, "always follow the direction of the greatest angle." By this is meant that, when a vein is dislocated by a fault, the angle formed between the vein walls and the fault plane should be observed. One of these angles is usually wider than the other, and Schmidt's law is to follow along the fault plane in the direction of the greatest angle. Thus, if a vein dips to the east at  $75^\circ$  from the horizontal, and if it be cut by a fault dipping at  $45^\circ$  from the horizon, the angle formed between the foot wall of the vein and the fault plane would be  $30^\circ$  and the angle between the hanging wall of the vein and the fault plane would be  $150^\circ$ . Then, according to Schmidt's law, the miner in search of his vein must follow along the fault plane in the direction of the greatest angle ( $150^\circ$ ), which is downward on the dip of the fault, when at an uncertain distance he will find his vein on the lower side of the fault. This so-called law is not infallible, and in the case of lateral as well as vertical displacement cannot always be relied upon. The physical condition of the wall rocks at the point of fracture often gives a hint as to the direction of throw.

THE Supreme Court of Montana said in part, in the case of the Butte & Boston M. Co. v. Societe des Anonymes de Lexington: "The right of an apex proprietor to pursue a vein passing from his side lines is dependent upon whether or not, as a fact, the part or mineral body of vein matter which lies outside of the perpendicular of the side lines of his surface claim is so preserved in its identity with the lode inside that it is part of the same vein, the apex of which belongs to the surface owner. \* \* \* On principle, the identity of the apex of a vein with its spurs and extensions must be the crucial test by which are to be fixed the proprietary rights to that vein and the mineral therein. \* \* \* The pursuit of the vein on its dip being then the right to be guarded, the identity of the vein pursued must be proven to make the right availing where it is contended the vein, after passing beyond the vertical planes drawn through the side lines of the surface boundaries of the location in which rests the apex, penetrates soil the surface of which is embraced within another location. Identity must always exist. Were there any departure from this rule, the miner might secure the benefit of more than he discovered, which was never contemplated by the law. \* \* \* Though a continuity of vein does not preclude identity of vein, yet identity does not necessarily include continuity. \* \* \* In this discussion, however, we do not mean to exclude the need of continuity sufficient to preserve identity. The application of the rule of identity should always be made so as to require the miner to trace his lode continuously if he depart beyond his extended side lines." The Supreme Court of Colorado, in the case of the Iron Silver M. Co. v. Cheesman, said: "Certainly the vein or lode must be continuous, in the sense that it can be traced through the surrounding rocks, though slight interruption of the mineral-bearing rock would not alone be sufficient to destroy the identity of the vein. Nor would a short partial closure of the fissure have that effect, if a little farther on it occurred again with the mineral-bearing rock within it." The courts properly insist upon the establishment of the identity and continuity of a vein, in pursuing the extralateral right, but identity is seemingly more important than continuity. It is admitted that the identity of a vein may be clearly shown in the case of a moderate dislocation by a fault, but the courts have never determined to what extent a vein may be faulted. There are known instances where a mineral vein or bed is faulted and the point where the fault commences is known. The displacement at first is small and the identity of the vein is positive, but half a mile distant it has become a fault of considerable importance and the ore body is dislocated by several hundred feet. An instance of this kind was found in the Little Cottonwood Canyon district of Utah.

## Trials of a Millman.

TO THE EDITOR:—In your issue of February 18th, I find a very interesting and instructive article on the trials of millmen, with some suggestions of means and methods for their relief and improvement in savings made in milling.

While I fully agree with the facts as stated, and with the suggestions made for benefiting the conditions, I think the writer might have gone further and been more explicit in defining the application of the methods advised, as they are all unquestionably along the right lines and are the most prevalent and important omissions in the construction and equipment of the modern mill.

Admitting and affirming that all the difficulties of different constituency of ores and of correctly sampling same exists in every mill, and that an even supply of water to the battery is important for all purposes, the crushing will not only produce coarse sand and slimes, but a product with a great variety of size and gravity of particles, for which a classification is absolutely necessary, not only separating the coarse and slime, but also segregating the different specific gravities, which, to be complete and effective, will require from six to ten sizes—the requisite number to be determined by the millman.

My experience has been if you ask the millman what percentage of different mesh pulp his batteries are producing, that nine out of ten will answer that they do not know—have never realized the necessity of knowing. But how can he tell what classification is necessary unless he does know, and how can he find out?

A very simple method that I have adopted is to take a nest of small screens, ranging from the mesh used on the battery in graduations of 20 mesh up to 200 mesh, place them in a column with the coarsest at the top, on slats over a tub, catch several buckets of pulp without allowing any to run over the top of the bucket and turn through the screens; then follow with a little clear water for cleaning purposes. Then separate the screens and weigh what is caught on each screen, settle and evaporate the water in the tub, and weigh the slime it contains. From the data obtained you can arrange your classification according to the number of your tables, in graduations of 20 or 40 mesh, from one table to the other, and know what proportion of the whole each table should receive.

The means of classification are of the greatest importance, and should be such as will produce the most favorable conditions for good work by the tables, which are:

First—Accurate sizing of particles according to specific gravity for each table.

Second—The regulating of water with each size to the least amount that will effect the separation on the table.

Third—To maintain absolutely even feed of both pulp and water to each table.

It is almost impossible to prevent some variation of discharge at the battery on account of some clogging of the screens by fine dirt and clay, and the necessity of frequently using the hose to wash them out and wash down the plates. Therefore, a sizer or classifier that works with a large volume and head above the draughts to the tables is most efficient, as the variations will not be felt; also, one by which the quantity of water coming from the battery and plates can be reduced instead of increased, and no loss of slimes go with the overflow.

This is one objection to this system of classification, the added water at each cone passing on and discharging with the finer sizes, where it is not wanted, and where the use of the smallest amount possible is of the greatest importance in effecting a high saving.

The regulating of the speed, which the writer demands, is of such great importance that no care and reasonable outlay should stand in the way of supplying it, and where steam power is used, a separate engine should, if possible, be provided and nothing but the concentrating tables be driven by it.

It is also of the greatest importance that not only a uniform speed be obtained (as the writer maintains), but, when the proper sizing and classification is had, means should be provided for graduating the speed of each table to the class of pulp it is handling. The use of an expansion pulley for each table, placed between the countershaft and the table, is very convenient and effective, and those who have not used them will be astonished when they do to see what effect even four or five strokes a minute will have on the action of a table.

The regulation of the stroke also has a decided effect on classified pulp. In concentrating without classification, the range of adjustment is limited, and the saving is also limited. The millman, who devotes the most study to conditions and the greatest care in application of method, will be the most successful; and the mine and mill owner, who secures the best man and gives him carte blanche in equipping the mill, will make the most money.

Los Angeles, Cal., Feb. 27. J. O. DIMMICK.

## New Rules for Forest Control.

Throughout the mining regions of the West the preservation of the forests is of greatest importance, and the laws and department rulings having a bearing on the use of the forests and their preservation are of interest to all mine owners. Following is a letter from the Secretary of Agriculture to the Forester, which gives the latest official information on this important subject:

TO THE FORESTER, FOREST SERVICE—SIR: The President has attached his signature to the following Act:

"An Act providing for the transfer of forest reserves from the Department of the Interior to the Department of Agriculture.

"Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That the Secretary of the Department of Agriculture shall, from and after the passage of this Act, execute or cause to be executed all laws affecting public lands heretofore or hereafter reserved under the provisions of section twenty-four of the Act entitled, 'An Act to repeal the timber culture laws, and for other purposes,' approved March third, eighteen hundred and ninety-one, and acts supplemental to and amendatory thereof, after such lands have been so reserved, excepting such laws as affect the surveying, prospecting, locating, appropriating, entering, relinquishing, reconveying, certifying or patenting of any such lands.

"Sec. 2. That pulp wood or wood pulp manufactured from timber in the district of Alaska may be exported therefrom.

"Sec. 3. That forest supervisors and rangers shall be selected, when practicable, from qualified citizens of the States or Territories in which the said reserves, respectively, are situated.

"Sec. 4. That rights of way for the construction and maintenance of dams, reservoirs, water plants, ditches, flumes, pipes, tunnels, and canals, within and across the forest reserves of the United States, are hereby granted to citizens and corporations of the United States for municipal or mining purposes, and for the purposes of the milling and reduction of ores, during the period of their beneficial use, under such rules and regulations as may be prescribed by the Secretary of the Interior and subject to the laws of the State or Territory in which said reserves are respectively situated.

"Sec. 5. That all money received from the sale of any products or the use of any land or resources of said forest reserves of the United States, and for a period of five years from the passage of this Act shall constitute a special fund available, until expended, as the Secretary of Agriculture may direct, for the protection, administration, improvement, and extension of Federal forest reserves.

"Approved February 1, 1905."

By this Act the administration of the Federal forest reserves is transferred to this Department. Its provisions will be carried out through the Forest Service, under your immediate supervision. You have already tentatively negotiated the transfer with the Commissioner of the General Land Office, whose powers and duties thus transferred I assign to you. Until otherwise instructed you will submit to me for approval all questions of organization, sales, permits, and privileges, except such as are entrusted by the present regulations to field officers on the ground. All officers of the forest reserve service transferred will be subject to your instructions and will report directly to you. You will at once issue to them the necessary notice to this effect.

In order to facilitate the prompt transaction of business upon the forest reserves and to give effect to the general policy outlined below, you are instructed to recommend at the earliest practicable date whatever changes may be necessary in the rules and regulations governing the reserves, so that I may, in accordance with the provisions of the above Act, delegate to you and to forest reserve officers in the field, so much of my authority as may be essential to the prompt transaction of business, and to the administration of the reserves in accordance with local needs. Until such revision is made, the present rules and regulations will remain in force, except those relating to the receipt and transmittal of moneys, in which case Special Fiscal Agents of this Department will perform the duties heretofore rendered by the Receivers of Local Land Offices in accordance with existing laws and regulations. The Chief of Records, Forest Service, is hereby designated a Special Fiscal Agent, and you will direct him at once to execute and submit for my approval a bond for twenty thousand dollars.

On December 17, 1904, the President signed the following order:

"In the exercise of the power vested in the President by Section 1753 of the Revised Statutes and acts amendatory thereof:

"It is ordered, That all persons employed in the field and in the District of Columbia in the protection and administration of forest reserves in or under the General Land Office of the Interior Department be classified and the civil-service Act and rules applied thereto, and that no person be hereafter appointed, employed, promoted, or transferred in said service until he passes an examination in conformity therewith, unless specifically exempted thereunder. This order shall apply to all officers and employees, except persons employed merely as laborers, and persons whose appointments are confirmed by the Senate."

This order classifies the whole Forest Reserve Service, now transferred, and places it under the civil service law.

In the administration of the forest reserves it must be clearly borne in mind that all land is to be devoted to its most productive use for the permanent good of the whole people and not for the temporary benefit of individuals or companies. All the resources of forest reserves are for use, and this use must be brought about in a thoroughly prompt and business-like manner, under such restrictions only as will insure the permanence of these resources. The vital importance of forest reserves to the great industries of the Western States will be largely increased in the near future by the continued steady advance in settlement and development. The permanence of the resources of the reserves is, therefore, indispensable to continued prosperity, and the policy of this Department for their protection and use will invariably be guided by this fact, always bearing in mind that the conservative use of these resources in no way conflicts with their permanent value. You will see to it that the water, wood and forage of the

reserves are conserved and wisely used for the benefit of the home builder first of all, upon whom depends the best permanent use of lands and resources alike. The continued prosperity of the agricultural, lumbering, mining and live stock interests is directly dependent upon a permanent and accessible supply of water, wood and forage, as well as upon the present and future use of these resources under business-like regulations, enforced with promptness, effectiveness and common sense. In the management of each reserve local questions will be decided upon local grounds. The dominant industry will be considered first, but with as little restriction to minor industries as may be possible. Sudden changes in industrial conditions will be avoided by gradual adjustment after due notice, and where conflicting interests must be reconciled the question will always be decided from the standpoint of the greatest good to the greatest number in the long run.

These general principles will govern in the protection and use of the water supply, in the disposal of timber and wood, in the use of the range, and in all other matters connected with the management of the reserves. They can be successfully applied only when the administration of each reserve is left very largely in the hands of the local officers, under the eye of thoroughly trained and competent inspectors.

JAMES WILSON, Secretary of Agriculture.

## Electrolytic Chlorination Process.

TO THE EDITOR:—In the issue of the MINING AND SCIENTIFIC PRESS of February 4, 1905, appears a reference to our treatment of the ores of the Ruby Mining Co. on Chopaca mountain, near Nighthawk, Okanogan county, Wash. Believing that this innovation in metallurgy will be of interest to many of your readers, we append the following details of the process:

The ore is crushed fine enough for a tube mill, dried and put in a hopper suitable to feed into the tube. This tube mill has inlet for chlorine at one end, and outlet for volatile substances (such as sulphur, arsenic and antimony) at the other. It is half filled with flint pebbles and the ore admitted. At the same time chlorine is admitted at the opposite or outlet end. Heat is applied, and the volatile chlorides, such as sulphur-chloride, are driven out and condensed. As the chlorine comes in contact with the ore all the base metals and the silver form chlorides. As the material reaches the outlet spiral, it is discharged into vats for leaching. The vessel then contains gangue mixed with free gold, and the chlorides of lead, silver, copper, zinc and iron. It is then leached with chlorine water for the purpose of dissolving gold. The solution then contains the chlorides of gold, iron, copper and zinc, and is then passed through cement copper to precipitate the gold; then is passed over granular zinc, and the copper is precipitated. The solution is then chlorinated again to make all iron present ferric. Then zinc oxide is added to precipitate the iron. The solution is filtered and then contains only zinc chloride which is electrolyzed to obtain chlorine and zinc.

The gangue that was left from leaching the original mass contains chlorides of lead and silver. It is then leached with hot brine to dissolve these chlorides, and when the solution becomes cold, the lead chloride and most of the silver chloride precipitates. The brine is then purified with sodium sulphide, which precipitates all the lead and silver as sulphides, which are then ready for cupellation. The lead and silver chlorides that were precipitated from the cooling brine may be fused and separated by molten lead and molten zinc, giving lead and silver as metals and zinc chloride as end products.

Zinc chloride yields zinc and chlorine by electrolysis from aqueous solution, or from fused mass. The chlorine is then returned to reduce more ore. For the purpose of starting, and to cover waste, chlorine is first obtained by the electrolysis of salt from solution, and at the cost of such power, as we understand this mine has, the expense will be about one-quarter of a cent per pound. The sulphur chloride will give up its chlorine to the pulverized ore and decompose it, giving all its sulphur in the free state, so there is not much loss of chlorine. The sulphur can be distilled from the gangue.

The ore of this mine according to the sample sent us analyzed as follows:

	Per Cent.
Insoluble gangue.....	79.350
Lead.....	0.333
Copper.....	5.180
Iron.....	2.716
Aluminum oxide.....	3.790
Antimony.....	0.252
Arsenic.....	0.553
Zinc.....	2.121
Calcium oxide.....	0.680
Magnesium oxide.....	0.254
Sulphur.....	3.786
Total.....	99.355
	Ounces.
Silver.....	596.46
Gold.....	.07

From the above, the complex character of the ore is manifest. Our process requires no concentration. Cleveland, O., Feb. 20. BAKER & BURWELL.

### Jeffrey Flexible Cable Car Haul.

Herewith is illustrated the wire cable car haul as installed by the Jeffrey Mfg. Co. at the works of the Beckley Coal & Coke Co., Beckley, W. Va. The wire cable haul, as illustrated, being flexible, can be used in short hauls, and is asserted to be of even greater

Jeffrey Flexible Cable Car Haul.

utility where the distance or length of haul is great.

At the Beckley plant the distance from the gathering point in the mine to the tippie is 350 feet. In this operation a single steel cable is used, which passes over an adjustable special cable wheel in the mine, while at the tippie it operates over two sheaves, connecting with a third located immediately underneath, which is set at right angles. These cable wheels are made with pockets which receive the special cable attachments and carriers, which are guided over, down and around the lower wheel, which acts as the main drive to the whole system. The features especially emphasized by the manufacturers are its design, the special dogs which are attached to the cable for carrying the car, the special clamps and the adjustable cable sheaves, all being protected by patents issued and pending and common only to Jeffrey installations. The Beckley plant is designed for a capacity of 2400 cars (each with a capacity of 1½ ton of coal) in ten hours. Special printed matter on this subject can be had by addressing the Jeffrey Mfg. Co., Columbus, Ohio.

The first large electric hoist for deep level mining on the Rand has been ordered for the Village Main Reef mine at Johannesburg. It will be placed at a vertical depth of 1100 feet, and will haul on a 1700-foot incline. The generating plant will be of 900 H. P., and the hoist of 500 H. P. From the 1100-foot level skips will be hoisted to the surface as formerly.

### Magnetite in the Blast Furnace.

To THE EDITOR:—Answering your note in your issue of the 4th inst. regarding the use of magnetite in the copper smelting blast furnace, I beg to say:

We are using this material as a flux or "dope" in the furnaces of the Montana Ore Purchasing Co. here in Butte, and have none of the troubles mentioned in the article quoted. Our material is a hard, solid magnetite, carrying usually 55% Fe and about 11% SiO<sub>2</sub>, much of this being contained as silica tes. The material is crushed to pass an ordinary 10x30 Blake crusher and then fed to the furnaces as needed.

I say it is used as "dope" rather than as flux. That means that we do not have to rely on this material for the iron for our matte, nor for all the iron for our slags, either, this iron being obtained from the coarse concentrates from the regular copper ores. The magnetite is used at irregular intervals, when in the judgment of the blast furnace foreman the condition of the furnace bottom, or the slags, indicates that a dose of iron will help the slags or speed the furnace up. This it does, and we see no difference in the action of this material on our furnaces over that obtained from the use of hematite. When used at all the magnetite is fed into the furnace 1000 pounds at a time, and during one day as much as six or eight tons is frequently fed to one furnace.

This would not represent an average, but illustrates the amount which may be used under our conditions without showing the bad features mentioned by your correspondent. In order that the proportions may be better appreciated, it is safe to say that the furnaces average about 150 tons of ore and about 300 tons of total charge (exclusive of coke) in twenty-four hours.

JAMES W. NEILL.

Butte, Mont., Feb. 21.

To THE EDITOR:—Replying to your inquiry of the 23rd ult., would state that the magnetite to which Mr. Lindgren refers, in "Genesis of the Clifton-Morenci Copper Deposits," was successfully used by us as a flux for a number of years in the smelting of oxidized ores for black copper. We have not used it in smelting for copper matte, otherwise we would have probably encountered the trouble you refer to.

JAMES COLQUHOUN,  
Arizona Copper Co.

Clifton, Ariz., Feb. 25.

### Gas Engine Hoist.

The accompanying illustration shows an 8 H. P. gas engine hoist built by the Corliss Gas Engine Co. of San Francisco, Cal. It was especially designed for a miner's prospecting plant, and has a hoisting capacity of 1500 pounds 160 feet per minute. The drum and the frame to which the engine is bolted are of steel, and wherever possible steel has been used in place of cast iron. This engine is operated with either gasoline, distillate or crude oil, and, it is claimed, can be run on less than 1 cent per horse power hour. A pulley is fitted to the shaft, which can be used for pumping, sawing and all general purposes. The weight is 2500 pounds.

Good mining records are obtainable by the employment of careful and experienced management, good machinery and good men. The best manager is he who properly accomplishes results at the least cost, whether these results are profitable or not. Managers of rich mines get more credit than they are entitled to, while the careful manager of a poor property is, as a rule, damned by faint praise.

### A Tailing Stacker for Hydraulic Mines.

The machine shown in the illustration is designed to handle the tailings from hydraulic mines, throwing the material 75 to 100 feet from the machine and stacking it from 40 to 60 feet high, and is also designed to handle boulders 10 inches in diameter. Its stated capacity is 2000 yards per day. It is placed at the end of the sluice, with a grizzly interposed between the sluice and the rock chute. The water and fines drop through the grizzly into the undercurrent, where the fine gold is saved, and the water carrying matter in suspension is run onto the ground or into settling ponds, according to location and conditions. In operation a stream of water sufficient to develop 35 or 40 H. P. is conducted to the water wheel attached to the shaft of the machine,

Tailing Stacker for Hydraulic Mines.

which runs at the rate of 250 revolutions per minute. The shaft is mounted in acme roller bearings, which need lubricating but once in six months and reduce the horse power necessary to operate the stacker. The manufacturer states that the machine can be set so that the material can be thrown in any direction or at any angle. It is made entirely of steel. The steel plates, where the greatest wear occurs, can be renewed at small expense and the construction permits of easy transportation. It is claimed that where a dump of 6 or 8 feet can be obtained the machine can be used, as the material is thrown back of the machine and onto the ground already worked. As the bank is worked the machine is moved, the length of the sluice remaining the same and the bank followed up.

The low dump permissible makes it possible to work many good hydraulic mines that are now idle on account of insufficient dump. It is also adapted to mines where a dam acceptable to the California Debris Commission cannot be built. The material discharged from the stacker forms a harrier or dam through which the water used in hydraulicking must percolate, thus reaching the stream, if there be any, virtually free from slickens or other matter in suspension.

The machine can be run by steam or electric power, the cost of installing, operating and maintaining being stated to be less than that of a good dam. It is also adapted to dredgers. This machine is manufactured by H. G. Comstock, 230 Montgomery street, San Francisco, Cal.

Gas Engine Hoist.

### Innovation in Tunnel Work.

Some of the most interesting mining engineering work undertaken in America has been done in and about the city of New York. Among the notable engineering works completed and in progress there are the new Croton aqueduct, the tunnels beneath the Hudson river, the rapid-transit subway recently completed, and the driving of a new railway tunnel in the borough of the Bronx. The latter work is thus briefly described in the Engineering News:

As a part of the depression and rectification work on the Port Morris branch of the Harlem division of the New York Central & Hudson River Railroad, a short tunnel is being driven under St. Mary's Park. The park is near 149th street and St. Ann's avenue, in the borough of the Bronx, New York City.

The two most interesting features of this tunnel work are the location and loading of drill holes, and the loading of muck with a steam shovel operated by compressed air. Steam shovels have been used before in tunnel work, but never, so far as we know, within the limits of Greater New York. The gneiss and mica-schist of New York break out in much larger chunks than the shales and sandstones of Pennsylvania, where steam shovels have been used in tunneling, and for this reason the spacing of the drill bores and the charging of the holes on the St. Mary's Park tunnel work will be of particular interest to contractors and engineers as furnishing a precedent for similar work in tough rock.

The top heading, Fig. 1, was first driven from

Fig. 1—Front View and Plan of Holes in Heading.

Fig. 2—St. Mary's Park Tunnel Section.

portal to portal, its dimensions being 8x12 feet, and the position of the drill holes being as shown. Both dynamite and joveite were used in the heading blasting—the dynamite being 60%, and the joveite of an equivalent grade. There was no material difference in the work done by the two kinds of explosives, pound for pound, and the average amount used was six pounds per cubic yard of rock. The heading averaged 4 cubic yards per linear foot.

The bench is being taken out in two lifts, as shown in Figs. 3 and 4, the upper lift or bench being kept just in advance of the lower bench. Two rows of holes are drilled in each bench, charged and fired in the order shown, the "a" holes being set off in the first blast, then the "b" holes, then the "c" holes. The resulting breaking up of the rock is excellent; the writer has never seen a better example of heavy blasting in a tunnel. The huge muck heap is attacked by a steam shovel, Marion Model 20, having a yard dipper. Before blasting, the shovel is hauled back about 100 feet by a line from the hoisting engine which handles the muck cars. These cars are each 5 cubic yards capacity, and average about 2½ cubic yards of solid rock per load. They are hauled out in trains of two by a hoisting engine, located in the approach cut, and up an inclined track supported on blocking and trestle, having a sufficient rise to carry the empty cars back by gravity. As soon as the loaded train passes out of the tunnel the

empty train rushes in. The muck is lifted in skips by a derrick located on the bank above the approach cut, and dumped either into cars or into a dump heap. This dump heap is used as a stock pile for

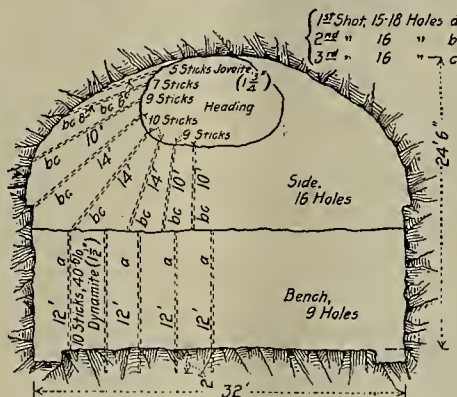

Fig. 3—Front View of Holes in Benches.

Fig. 4—Side View of Holes in Benches.

the crushing and concrete mixing plant. The shovel is now working about 350 feet from the south portal of the tunnel and is giving perfect satisfaction. The crew operating it consists of the two shovel men, four pit men and a pit boss.

### Getting Subscribers.

Some of the experiences of our corps of subscription solicitors throughout this west half of America makes interesting reading at times. The following is part of a recent letter from a Colorado subscription solicitor. It was not written for publication, but furnishes a good illustration of part of the work on a technical journal of which little is ever said. Just as part of the day's work he writes:

I left Breckenridge in the afternoon, walked 8½ miles to the Quandary mountain mill, where I stayed over night; next morning started for the Ling Star mine, on North Star mountain. As the crow flies this mine was 2½ miles from the Quandary mountain mill; as I had to go it was considerably farther. Instead of following the wagon road over Hoosier pass I went up the side of the mountain, catching hold of bushes and trees to keep from rolling back. After an hour I landed on top of a mesa, or plateau, and struck a trail up the side of the mountain to the main trail to the mine. When I reached the main trail I was in Park county, on the southern slope of North Star mountain, but close to the top. For over 3 miles I followed this jack trail over the rock slides and snow banks. The trail was built close to the summit of the mountain, but on the south side and all the way in a rock slide. About a mile from the mine I saw a man a short distance below and waited until he came up. He proved to be the mine foreman on his way to the mine. We traveled together along this trail to the top of the mountain, and then a zig-zag trail down on the north side of the hill to the mine. At 11 o'clock we got to the boarding house, where I had dinner. At 1:30 p. m. I started for Alma, 10 miles distant. Instead of going back by the trail I left the trail at the top of the mountain and went down the south side of the hill to another mine in operation at the foot of the mountain in the canyon. Leaving this place I started down the canyon for my destination, stopping on my way at a mill at Montgomery, and so on to Alma, having walked up hill and down and in rock slides a distance of 14 miles. But I got what I went after.

Of course, the scenery was grand, and that made me forget how tired I was. On the north side of North Star mountain, and 3000 feet below the Ling Star mine, is Blue lake, the headwaters of Blue river, which flows toward the Pacific. On the south side was the headwaters of Platte river, which wends its way to the Atlantic. I was on the continental divide, or backbone of the continent (a great place to find subscribers, but that is the place they usually get). Some of the rock dumped from the Ling Star mine finds its way down to Blue lake. It makes a fine dumping place.

### Revival of Mining at Unionville, Mont.\*

In the early days of mining in Montana, one of the most noted districts was that about Unionville, in the vicinity of Helena. After a number of years of active mining, during which the placers of Alder gulch added many millions to the gold production of Montana, and such mines as the Whitlatch-Union, Snowdrift-Penobscot, and other mines became famous, there came a period of inactivity. This section is now the scene of a marked revival of the mining industry, and the following from the report of the Montana State Inspector of Mines, James Byrne, soon to be issued, is of interest in this connection:

For a period of ten years, beginning in 1867, there was great activity in quartz mining in the vicinity of Unionville, and it centered around the Whitlatch-Union mine, discovered by James Whitlatch, and later worked by the National Mining & Exploring Co.

This company is credited with having taken out over four millions of dollars in seven years. In 1877 the mine closed down, and was allowed to fill with water. Subsequent operations were confined to the territory which the water did not cover, and leasers or tributaries worked whatever could be most easily reached—the pillars of ore which yet remained in the mine, and the waste in the stopes, which, by sorting, yielded good wages to the men thus employed.

Almost every summer since the company operations were suspended, the old 10-stamp mill has been at work, part of the time, crushing the ore taken out of the mine by leasers the preceding winter. This accounts for the fact that Unionville has never been entirely deserted, quite a number of people gaining their living wholly or in part out of this mine. And now the old camp bids fair to be one of the best of the smaller camps in the State.

Union Hill occupies the divide between Oro Fino gulch and Grizzly gulch 4 miles south of Helena, and through this hill runs the belt of East and West lodes which furnished the gold to the wonderfully rich placer diggings of Last Chance gulch. The Union Lode may therefore be justly termed the "Mother" of the placers round about Helena, to the amount of \$28,000,000. Both Oro Fino and Grizzly gulches have a general northerly course, cutting the lodes or veins at nearly right angles, and it is plain that by the simple process of denudation, the quartz of the vein was made to give up the free particles of gold, which so enriched the gravels of Last Chance gulch, lower down.

Of all the veins cut by these gulches, the Union No. 2 vein, constituting the central portion of the property of the Whitlatch M. Co., was the richest vein, and produced the most money in the shortest time. At one time there were seven stamp mills in operation in and around Unionville, and the ore mined to supply these mills was always from the smaller and richer streaks of quartz, while the large masses of low grade ore were passed by, and could not be handled, owing to the lack of a suitable and cheap process of treatment. The cyanide process now affords a remedy for this lack of utilization of the great mass of mineralized granite lying between the veins, as well as the low grade vein stuff which has hitherto been thrown aside as waste.

The Big Indian mine, on the same belt, 2½ miles further east, has demonstrated with its economically run 60-stamp mill, that a very low grade material can be made to pay a profit, and has had much to do with setting the pace for other mining operations on the "Mother Lode" of the Unionville district.

The contact between the limestone and the granite occurs on the northerly side of Union Hill, and has a general east and west course, crossing both Oro Fino and Grizzly gulches, and the mineralized belt in the granite lies to the south of this contact, and is an average distance of one-half mile away from it.

The same class of lodes extends over into the "Park," as the locality west of Grizzly gulch is known. Here development has never gone more than 200 feet in depth, and, whenever what would now be called a very moderate flow of water was encountered, work was suspended. A number of independent operations on the Park lode, which appears to be the western extension of the Union lode, were conducted up to the year 1880, but none of them did more than scratch the surface, and mill the ore from richer vein streaks easily accessible.

When, in the spring of 1904, Canoll & Martin began operations upon the Whitlatch mine, a new impetus was given to mining in the vicinity of Unionville. Having secured the property of the National Mining & Exploring Co., as well as a number of adjacent claims, they began in May, 1904, under the direction of Frank L. Sizer, who is general manager of the new company, the sinking of a vertical two-compartment cage shaft, and on Nov. 8th, it had been sunk to a depth of 415 feet. Since that time vigorous development by drifting on the vein has been in progress, with what are understood to be favorable results.

As the old inclines by which the National Mining & Exploring Co. had worked its mine were in a dilapidated condition, it was deemed best to sink a

\* See illustration on front page.

new shaft at a point where none of the old workings would be directly encountered, and development has proceeded as if the ground were virgin. The wisdom of this policy has already been demonstrated, and as the old workings had reached a depth of not more than 300 feet, vertical from the surface, considerable new ground has already been opened by the new 400-foot shaft. A considerable flow of water has already been met with, and more is expected when the various levels shall have opened more ground on the vein. A No. 9 Cameron pump at the 300-foot station, and a No. 7 sinking pump at the bottom, are kept in constant operation to handle the water.

The surface plant put upon the Whitlatch mine, by the new company, consists of a pair of boilers, a double cylinder first motion hoisting engine good for 700 feet of depth, a four-drill straight-line air compressor, covered with a substantial iron roofed building. Adjacent to this are blacksmith shop and carpenter shop, with boarding house, bunk house and office building, all new, and thoroughly built.

There is an old 10-stamp mill on the property, which has thus far not been operated by the new company. It is expected that with further favorable development in the mine, the company will be in a position to start the construction of a new and modern mill by the summer of 1905. It will be a plate mill, combined with cyanide treatment for the tailings, but the size has not yet been determined. It is expected that the additional recovery of value from the ore over the old style of milling in vogue at the time the mine was closed down, in 1877, will constitute in itself a very fair profit on the whole operation.

Future development of the Whitlatch mine will be watched with interest, and as work goes on, there will be, unless all signs fail, encouragement to other mining operations in the vicinity of Unionville, and an era of prosperity for the whole neighborhood may be reasonably looked for.

### Gold Dredge Efficiency.

TO THE EDITOR:—I have read with much interest the abstract of the annual report of the Oroville Gold Dredging & Exploration Co. in your valued issue of February 18. It contains figures of the greatest possible value to the dredging industry. There is only one point which appears to need further data to make it valuable. Under the head of extraction the report reads as follows:

"The prospect value of the dredged area, based on the average value of the holes in and near the dredged area, was 16.64 cents. The extraction table herewith attached, which is computed on these figures, makes the extraction 74% of the prospect value."

I take this means of asking Superintendent C. H. Munro what equivalent diameter he used when calculating the results of his original prospecting, so that the mining and engineering profession in general may have the benefit of his reply. Without this explanation the majority of readers would get the impression that the gold-saving efficiency of dredges did not exceed 74%, forgetting that the total efficiency is subject to two factors, one being the quality of bedrock (this factor being to a large extent independent of the dredge), and the other the actual efficiency of the separating and gold-saving devices used. This, in the case of the Risdon tables and revolving screen, with which I have had the most experience, is certainly far above 74%, as proved by assaying the tailings from the stern of the dredge. The combined efficiency or percentage saved of the actual value in the ground cannot be calculated, except approximately, owing first to the impossibility of arriving at a definite diameter to represent accurately the actual amount of ground taken out by the sand pump per foot of hole drilled, and secondly because the amount actually treated bears such a small percentage to the ground dredged that results averaged from the prospecting can only be approximate. In the above I do not wish for a moment to imply that prospecting properly done does not give a very close approximation to results which can accurately be obtained in dredging. I have known engineers, prospecting with a 6-inch drill, take as a basis of calculation diameters varying from 6 inches to 8½ inches to represent what they considered the actual area of ground taken out by the sand pump. Under exactly similar conditions, if the dredge showed an extraction of 50% when a 6-inch hole was used as a basis, it would have shown 100% extraction if the basis had been 8½ inches. To arrive at a close approximation of what may really be expected from a dredge, given a bedrock which can be cleaned up, and systematic and careful prospecting, I have kept careful records of various experiments of large quantities of ground, and have evolved the following formula:

Let  $c$  = value of gold in cents taken out of prospect hole;  
 $d$  = depth of hole in feet;  
 $v$  = value per cubic yard in cents which dredge ought to recover;  
 then  $v = \frac{100 \times c}{d}$

The constant 100 is an arbitrary figure, but it will

be found to represent approximately a 7-inch diameter.

If Mr. Munro will give the data on which he based his prospecting it will be greatly to the benefit of all dredge operators, as the more data proved up by actual results the better, and the combined experience may modify the constant given in the above formula—to make it agree more closely with average results.

R. H. POSTLETHWAITE.

### Rotary Melting Furnace.

The Rockwell rotary melting furnace is constructed with two independent chambers, located end to end, communicating with each other and having a burner

Skimming.

Rockwell Rotary Melting Furnace.

at each outer end. The chambers are mounted on legs resting on a base; both chambers charged with metal. One burner is operated at a time, firing and melting occurring alternately from left to right and from right to left. The spent gases escape from the live or primary chamber through the neck into the secondary chamber, where the heat is partly absorbed by the charge of metal in that chamber before being discharged into the open air. When the live chamber has completed its melt the fire is reversed, the secondary chamber becoming the live chamber. This operation of alternately charging, melting and reversing may be continued indefinitely. The two chambers forming the complete furnace are of steel; they are divided longitudinally through their axis, hinged on one side and bolted together through their flanges as shown. Each chamber at its center has a port for charging and pouring the metal. Each port has a hinged, tight fitting steel cover, held down during operation by two steel clamps. Each cover has a vent opening through its center which may be closed by a hinged cap and clamp. The chambers are mounted horizontally on rollers; the outer ends provided with worm gears and hand wheels for revolving and pouring. An oil or gas burner is placed at the outer end of each chamber. The burners are permanently fixed in position, are provided with valves and unions and can be easily removed if desired. The chambers are lined with a refractory material rammed in bulk into the half shells separately around a form, as sand is rammed around a pattern in a mould. The forms are then removed,

the shells closed after the fashion of a clam shell, and the linings are burned in place in the furnace from the heat of the burners.

In addition to melting brass, bronze and copper, it is designed for melting the product of the cyanide plant with intent to make it possible for the cyanide operator to reduce the product. The Pacific coast representative is J. C. Martin, Jr., 117 New Montgomery street, San Francisco, Cal.

STAMPS weighing 1000 pounds were used in California at the Allison Ranch mine, near Grass Valley, as early as 1870, also at the Rocky Bar mill. The Sierra Buttes mill, near Downieville, had twelve stamps of 640 and 600 pounds respectively. The drop was from 9 to 12 inches, sixty to sixty-seven drops

### Flodin Self-Oiling Wheel.

Herewith is illustrated the Flodin self-oiling car wheel, showing its general design. The annular chamber formed by the two webs is connected by two slot cores with the bore of the wheel. This chamber is filled with cotton waste, wool, or similar material, which can be readily soaked with oil. To oil the wheel the pipe plug is unscrewed and the waste in the chamber soaked with oil. These wheels are manufactured exclusively by the Lake Shore Engine Works, Marquette, Mich.

Flodin Self-Oiling Car Wheel.

## Mining and Metallurgical Patents.

PATENTS ISSUED FEBRUARY 21, 1905.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

MACHINE FOR CRUSHING ORES OR OTHER USES.—No. 782,264; D. J. Nevill, Salt Lake City, Utah.

In machine for crushing ores, etc., combination with pair of rolls and movable bearing at each end of one of rolls, of spring for each of bearings, two pressure plates which are independently movable and between which spring is supported, and means for transmitting movement of bearings in opposite direction to other plate, and adjustable rigid abutment for plates farthest from bearing.

ROCK DRILL.—No. 782,429, R. Temple, Denver, Colo.

In rock drill, combination of cylinder portion, reciprocating piston movably mounted therein, rifled nut in engagement with piston head, rifled bar in engagement with nut and provided with radially arranged face ratchet at its outer end, second radially arranged face ratchet frictionally held in cylinder head, stem portion therefor extending through cylinder head and provided with threaded end portion, threaded nut on threaded end of stem portion, yielding washer inserted between second ratchet and cylinder head to hold same in frictional engagement with cylinder head, and spring mechanism engaging first named ratchet, so as to normally hold it and thereby rifled bar in engagement with second ratchet.

HYDRAULIC LIFT.—No. 783,177; G. F. Cluff, Lodi, Cal.

In hydraulic lift, combination with movable uprise pipe, of slotted receptacle into which uprise pipe discharges, size of pipe being less than size of slot, means carried by uprise pipe for automatically closing unoccupied portion of slot, supply pipe lead-

ing to lower end of uprise pipe and nozzle for directing fluid from supply pipe into uprise pipe.

CONCENTRATING APPARATUS.—No. 783,221; O. B. Perry, San Francisco, Cal.

In concentrating apparatus, combination of screen, series of collecting tables located below and arranged successively lengthwise screen, distributor comprising series of independent pan sections successively arranged and located between screen and tables, and plurality of independent troughs extending from receiving end of screen lengthwise along series of pans and tables, all of troughs leading from common receiving point and delivering separated portions of material to separate pans at different distances from point.

ORE CONCENTRATOR.—No. 783,304; M. E. Parks, Torreon, Mexico.

Ore concentrator, comprising outer structure transverse forward and rearward vertical partitions dividing interior thereof into concentrator box, tailings box, and slimes box, and vertically reciprocatory jigger in concentrator box, combined with means for operating same, rearward partition being less in height than walls of structure, and forward partition less in height than rearward partition, inner side of jigger being also less in height than outer side.

ORE CRUSHER.—No. 783,323; F. P. Snow, Los Angeles, Cal.

In rock crusher having suitable hopper or receptacle for rock, vertically removable stationary jaw, adjustably secured at lower end within frame; vibrative jaw mounted at upper end upon eccentric driving shaft; independent vibrative toggle pivoted in plane below free end of vibrative jaw and having outer end located within lower end of jaw; and spring connected with vibrative jaw and with frame; whereby circular or gyratory movement is imparted to upper end of vibrative jaw and lower end of same

caused to describe arc of small amplitude, imparting oscillatory and vibrative movement to lower end.

PROCESS OF SMELTING REFRACTORY ORES.—No. 782,922; E. F. Price, Niagara Falls, N. Y.

Process of producing calcium carbide by interposing charge of calcium compound and carbon as resistance conductor between electrodes, one of electrodes being of metal and comprising liquid portion and solid portion, electrically heating charge to temperature requisite for reduction, and cooling solid portion of metal electrode.

ATTACHMENT FOR KEEPING SCREENS IN GOLD QUARTZ MILLS CLEAN.—No. 782,861; C. G. Lidman, Lead, S. D.

Combination with mortar screen, of bail having side arms hinged to mortar frame and connected to moving part of stamp to effect impact between cross bar of bail and screen, which by means of combination set forth.

ELECTROLYTIC PROCESS OF REDUCING METALLIC SULPHIDES.—No. 782,894; C. E. Baker and A. W. Burwell, Cleveland, Ohio.

Process of reducing metallic sulphides, supporting sulphide within electrolyte of molten chloride and in proximity to anode, passing electric current from anode through electrolyte, and causing electrolytic chlorine to react on sulphide and displace sulphur.

QUICK RELEASE DEVICE FOR ATTRITION OR OTHER MILLS.—No. 782,933; J. Waldron, Muncy, Pa.

Quick release device for grinding mills comprising, in combination with fixture and movable bearing for shaft of one of grinding disks, dead point elbow lever having shorter arm pivoted to fixture, and bowed link curved over pivot of lever and pivotally connecting elbow of lever with movable bearing.

## Bending Stresses in Wire Ropes.\*

Written by SAMUEL DRESCHER.

This paper relates to bending stresses as they occur in the wires of ropes bent around sheaves in the operation of hoisting machinery, inclined planes, cable railways and elevators, etc. It is herein assumed that the sheaves employed in such work are of diameters commensurate with the diameters of the ropes wound around them. According to a rule long since adopted in practice, sheave diameters shall equal, or exceed, forty-eight diameters of the corresponding ropes—that is to say, that for every quarter inch of the diameter of the rope, 12 inches are to be allowed for the diameter of the sheave. That this ratio is adequate is proved by the fact that when during the service of a rope in connection with a sheave of such diameter a wire breaks, it does not immediately part, but the broken ends remain in touch for several days and so close to one another that the break is detected only upon very careful inspection when the rope is at rest. From this we are justified to infer that the grip the wires have on each other, by reason of the twist, is such that those ends are held close together even while the rope passes around the sheave. On the other hand, it is obvious that if the ratio between sheave and rope diameters were only 24 to 1, the fractured ends of that particular wire would part sooner, owing to more severe bending, than with large sheaves. What the smallest diameter is that will yet answer can be ascertained by experiment only. Moreover, as the ratio of 48 to 1 is in most cases permissible, with reference to local conditions, we take it for granted that the ropes and sheaves considered in our investigations are of right proportions.

It is not the intention herein to undertake to ascertain the effect of bends that cause permanent stretches, as, for instance, loops and kinks, but these investigations are limited to the consideration of working conditions as usual in practice. Abrupt bends cause lateral spreading of the strands and consequent flattening of the section of that rope. A rope repeatedly subjected to such treatment would rapidly disintegrate.

I am not aware that ever any extensive practical tests were made toward establishing the effect that bending has upon the stress among the strands and wires of a rope. The experiments made in this direction were not pursued far enough to yield definite and reliable data.

It is in the interest not only of the users but also of the makers of wire rope that tests be made in this line, under conditions like those in practice. The parties most competent to do this are the manufacturers of wire rope.

In Kent's "Pocket Book for Mechanical Engineers" is given a formula for the calculation of bending stresses in wire ropes. It has also tables containing the results of calculations for various sizes of ropes and sheaves; but in that formula no cognizance is taken of the load hanging on such a rope, whereas, in fact, it takes more effort to bend a rope if taut than if slack.

It seems that this formula was made under the impression that in bending a rope the conditions are about the same as if bending a solid bar; for, according to these tables, the stress produced in the wires of a rope 2 inches in diameter, bent around a sheave 8 feet in diameter, is 57,000 pounds. If this were correct, the breaking of ropes on inclined planes, elevators, etc., would be of daily occurrence, and necessarily the use of wire ropes for such purposes would have to be abandoned. The fact is that the conditions prevailing in a wire rope while it is being bent differ very much from those in a bar subjected to the same operation. If we take a bunch of straight wires, arranged as in Fig. 1, tie them near one end by a tight-fitting ring into a cylindrical group, so that the wires can not shift relatively, and then bend that bunch, as shown in Fig. 2, the loose ends of the individual wires will not flush any more, as they were before bending, but, instead, the wires on the concave side of the curve are projecting, while those on the convex side are retreating, and all wires between concave and convex side follow more or less according to their situation in the bunch with relation to the neutral axis.

The resistance experienced in bending that bunch of wires is equal to the sum of the resistance of the individual wires, for each wire acts as a spring, and if the bunch consists of 100 wires its total resistance equals that of 100 springs each of the strength of a single wire. Now, let us take another bunch of wires of same number and size, but to have both ends firmly bound, as in Fig. 3. If we try to bend this bunch, we encounter many times the resistance we found in the bunch having one end open. This difference arises from the circumstances that in the bunch with fixed ends the wires can not accommodate themselves to the difference in length between inner and outer curve, but must necessarily stretch and contract, or buckle on the concave side, as in Fig. 3; but to do any of these acts requires much more effort than in the case of Fig. 1, where the wires could adjust themselves to altered conditions. Now, let us see what happens if we bend a rope of, say, 2 inches diameter,

around a sheave. Fig. 4 shows a fragment of wire rope that consists of six strands wound around a hemp core. As those strands are laid around the center in screw-thread fashion, all are subjected to precisely the same distorting and straining effects; consequently, whatever happens to one of these strands happens to all; therefore, we shall confine ourselves to the consideration of one strand instead of six of them.

Fig. 4 shows how a single strand lies around the hemp core. Its length is that of one turn around the core. The length of such a turn usually equals six diameters of the rope. Thus in a rope of 2 inches diameter the difference between corresponding points in one and the same strand is 12 inches.

By the act of bending, the point C of the strand is pressed against the rim of the sheave, the arc DCE flattens and the space DE spreads. If, at this occa-

Fig. 3.

sion, the points D and E were firmly held, the flattening of that arc could not occur, except to the extent that the compressibility of the material in the strand would permit. But since the points D and E are not fixed, and that the arcs AD and EB are in tension, and, further, that through the bending of the rope the chords AD and EB must expand so much as the chords DC and EB must contract; therefore, compression can not manifest itself, because any pressure at C must necessarily forward the local surplus towards points A and B. Hence the tension that occurs under ordinary conditions in the fibers of the convex side of a bent bar is, in the case of a rope, neutralized in the manner that the increment which the upper fibers lack is drawn from the concave side of the rope, whence an equal increment is displaced, by reason of the shortening of the arc DCE, contingent to the act of bending.

Compression in that arc DCE could take place only under the condition that the points D and E act as abutments; but, since these points readily yield, therefore, the surplus in arc DCE is at once transferred beyond the points D and E, to where it is required to prevent tension.

In this manner the bending of the rope takes place without severe stress in any part of the strand, because the increase in the outer circumference over that of the neutral axis of the rope is supplied by the corresponding decrease of the inner circumference. This compensation occurs locally, within every turn of the strand. The tendency to pull in the upper part is equal to that to shove in the lower part, and as both these forces lie in one and the same line and act in the same direction, therefore, neither opposes the other, but, on the contrary, they act in accord, with a common result. Hence, as far as these two forces are concerned, the movements within the strands would meet with no resistance at all, but owing to the fact that all strands are in close contact with each other and the rope is in tension due to the work it performs, therefore, there is a certain amount of friction to overcome when the strands adjust themselves to altered conditions.

Considering a 2-inch rope, and a sheave of 8 feet diameter, the difference between inner and outer circumference of the coil of rope, as laid on the sheave is  $4 \times 3.14 = 12.56$  inches = 1.04 ft, say, 1 foot. But the rope as laid around the sheave, measured along its neutral axis, is already  $2 \text{ inches} \times 3.14 = 6.28$  inches = 0.52 foot, longer than the circumference of the sheave, therefore, the elongation that occurs on the convex side of the rope during one revolution, is  $\frac{1}{2}$  foot, and in accord with this, the contraction on the concave side of the rope is also  $\frac{1}{2}$  foot, and likewise is also the whole adjustment during one revolution of the sheaves,  $\frac{1}{2}$  foot of all of which compensation takes place in the manner that the excess of the concave side is shifted to the convex side, and this takes place while the rope changes from a straight line to a circle. This motion is the aggregate of all motions in one strand that occur during a full revolution, and must take place under the pressure the rope exerts against the rim of the sheave which in turn reacts upon the rope and its strands. The resistance that opposes this motion is friction among the strands as they rub against each other.

The intensity of this friction depends upon the

pressure applied and the coefficient of the materials in contact. The coefficient of a steel rope upon a cast iron finished surface is 0.13. To be entirely safe, let us assume it to be 0.15.

The pressure that a rope exerts upon the circumference of a cylinder, if no matter what diameter, is  $2 \times 3.14 \times P$  per full coil. In this formula P represents tension in the rope due to its load. In the present instance let us take that tension at 30,000 pounds. Hence the aggregate pressure that one coil exerts upon the circumference of a cylinder, or sheave, is:  $2 \times 3.14 \times 30,000 = 188,400$  pounds. The circumference of an 8-foot diameter sheave is 25.13 feet. Hence the pressure upon 1 foot of circumference of this sheave is 7216 pounds, or say, 7200 pounds.

In a rope of 2 inches diameter a strand makes one winding around the core in 12 inches; therefore the compensation between compressed and pulled parts

of that strand must also take place within the length of 12 inches, and as this compensation is continuously occurring and that there are always exactly 12 inches of that rope affected, it is evident that the resistance opposing that readjustment is the friction produced by the pressure upon 12 inches of that circumference of the sheave, but since this pressure is 7200 pounds, the friction thus produced is  $7200 \times 0.15 = 1080$  pounds. As there are six strands in the rope and at all times engaged in the act of adjustment, we must multiply the resistance by six and thus get  $6 \times 1080 = 6480$  pounds as the total bending stress in the rope.

The power consumed in doing this bending is the bending stress multiplied by the amount of motion in the strands during the process of adjustment in one revolution. We saw before that the whole movement of the strands within one coil of the rope on the sheave is 0.5 foot, consequently the work of bending is  $0.5 \times 6480 = 3240$  foot pounds.

Applying this to a practical case, say, an incline plane of 1000 feet in length, or a shaft of this depth, the same sheave will make  $1000 \div 25 = 40$  revolutions, and as it takes 3240 foot pounds per revolution, the power consumed during one run in performing the work of bending the rope is  $40 \times 3240 = 129,600$  foot pounds. If this run is made in one minute, the power spent is  $129,600 \div 33,000 = 3.93$ , say, 4 H. P.; if made in two minutes it takes 2 H. P., etc.

If, for example, we were to use a sheave of only 4 feet diameter, the total pressure the rope would exert upon the rim of the sheave is the same as if the diameters were ever so large; but as the circumference of the sheave is only half as much as that of 8 feet diameter, therefore, the pressure per lineal foot of the rope is twice as great, and, consequently, the friction opposing the adjustment of the strands is double that in the other instance. This alone is sufficient reason to provide large diameter sheaves, but in addition to the double friction, we must take into consideration also that the 4-foot diameter sheave by reason of having but half the circumference of the 8-foot sheave must take twice as many revolutions for a given length of hoist as the latter, and since the amount of adjustment per revolution is the same with sheaves of all diameters, therefore, the energy consumed in using a 4-foot sheave is four times that required with an 8-foot sheave. In short, the resistance opposing the adjustment of the strand grows inversely with the diameter of the sheave and the energy required to accomplish that adjustment grows inversely with the square of the diameter of the sheave. Both instances refer to the same velocity of the rope.

In connection with the bending act it is to be said that the straightening of the rope does not require any external force, because in the act of bending the elastic resistance of the strands must be overcome, whereby energy is stored in those strands in same manner as by compressing or stretching a spring which resumes its original state upon being released. Therefore, the energy required to straighten the rope is imparted to the rope while it is being bent.

It stands to reason that there is a limit to the compensating capacity of the strand in a rope, but where that limit lies can be determined only by actual trials under working conditions. This task by right

\*Trans. Eng. Soc. of W. Pa.

falls upon the manufacturers of wire rope, in whose interest it is to furnish the customers reliable information concerning the proper use of wire rope.

Following is a comment on the above article by Wm. Hewitt, C. E., in the Engineering News, and as most of the data in Mr. Drescher's article were compiled from tables prepared by Mr. Hewitt some years since, is of interest:

The formulae given in Kent's "Pocket Book" for determining the bending stress in wire rope corresponds very closely with the formulae given by other authorities, and differs from the others in the fact that it makes allowance for the double spiral lay of the wires, and the conditions of bending are not considered the same as that of a solid bar. This formula simply gives the bending stress, to which the load stress is added in determining the total stress.

Taking the case of a 2-inch rope on an 8-foot sheave, the bending stress of which is given in the table calculated from the formula referred to as 57,000 pounds, I cannot see why Mr. Drescher should draw the conclusion that he does, because the maximum stress that such a rope made of steel wires would safely sustain is very much greater than 57,000 pounds. The conclusion arrived at in Mr. Drescher's investigation, that there is a compensating action in the wires whereby the bending of a wire rope takes place without severe stress in any part of the strand, owing to the tendency to pull in the upper part being equal to that to shove in the lower part, is not borne out by practical results.

After many years' experience with wire rope, I am convinced that the formula given in Mr. Kent's book is correct and reliable.

## Gold Mining in Rhodesia.

NUMBER V.

Written for the MINING AND SCIENTIFIC PRESS by F. C. ROBERTS.

Continuing the consideration of the expense of milling, the several items constituting this expense are as follows:

MILLING.			
	Total Cost.	Cost Per Ton.	Total Cost, %

A Modern Equipment on an Ancient Mine in Rhodesia.

CYANIDING. — Generally speaking the ores thus far produced in Rhodesia present few metallurgical difficulties.

In most cases the veins produce typically free milling ores. In fact, upon the properties with which the writer is connected, the highest grade of tailings produced is valued at \$3 per ton—this from an original product of \$16 to \$18 per ton.

If the mill were operated with a view to high plate extraction and the tonnage sacrificed the grade of tailings would be even less. The sand, if fresh, lends itself freely to cyanide treatment at a comparatively low cost per ton, while if highly oxidized, through a decomposition of the salts, as is often the case when working in close proximity to the "old workings," a small additional cost is incurred in neutralizing.

The consumption of stores upon a cyanide plant of 2800 tons per month capacity, measured over a period of twelve months, is given below:

CYANIDE STORES.			
Stores.	Quantity.	Total Cost.	Cost Per Ton.
Borax.....	457 lbs	\$ 134 47	\$ .0048
Carb. soda.....	120 lbs	9 24	.0004
Grease.....	131 lbs	16 78	.0006
Nit. acid.....	5 qts	38 41	.0008
Sil. nitrate.....	2 lbs 4 oz	30 67	.0010
Cyanide.....	21,056 lbs	6,570 25	.2294
Lime.....	452 bgs	1,760 25	.0614
Sulph. acid.....	63 jars	589 22	.0204
Zinc.....	7,283 lbs	1,119 33	.0392
Sundries.....		579 42	.0202
Totals.....		\$10,851 82	\$ .3782

In the construction of the double-treatment cyanide plants erected in this country, no new features are embodied over those included in this style of plant of five years ago. The time of treatment varies with different ores, depending largely upon the character of the gold being dealt with. In some instances which have come under the notice of the writer, where the gold appeared to be coated with a very thin film of iron sulphide, as much as twelve days have been consumed in dissolving, but the usual treatment extends over a period of from three to four days.

A great variation is shown in the fineness of the gold produced from cyanide slime. Often, due to the preliminary method of treatment, gold as low as 250 fine and as high as 900 fine is produced.

It is quite possible and inexpensive to produce gold as fine as 930 to 940 from cyanide slime by using Burnett's flux, which is here given:

### AFTER ACID TREATMENT.

	Parts.
Slime.....	100
Fused borax.....	20 to 35
Manganese dioxide.....	20 to 40
Sand.....	15 to 40

The addition of a cyanide annex in a country of free-milling ores may be questioned, and, no doubt, rightly so in some cases; but it is contended that if the grade of tailing will in the first place pay for treatment it is an advantage, in that it is possible to largely increase the capacity of a given number of stamps, with a corresponding decrease in the costs per ton.

The results of operating a cyanide plant of 2800 tons capacity per month, extending over a period of twelve months, is here given:

CYANIDING.

(TO BE CONTINUED.)

## The Mammoth Diamond.\*

Since the announcement of the discovery at the Premier mine, near Pretoria, of the "largest diamond" recently, I have received many applications from various sources for information concerning it.

The telegram giving advice of the finding of the stone conveys no particulars beyond stating the weight and that the quality of the stone is "good." The weight is quoted as being 3032 carats, which is equivalent to 20.013 ounces, or 1 pound 8 ounces, troy. For the purpose of weighing diamonds, one ounce troy consists of 151½ carats, and not 120 carats as in weighing gold.

It is impossible to give any opinion of the value of the diamond without actually handling it and making a careful examination of it. The value depends—

1. On the color and purity of the material.
2. On the freedom from imperfections.
3. On the shape.

The word "good" used in the telegram to describe the quality of the newly found diamond certainly does not convey that the stone is faultless, or very fine, but rather that it is just "good." Perhaps, however, this may be due to a natural modesty on the part of the company, and that it will possibly turn out to be of superb quality in every respect.

If the stone be free from imperfections, and an advantageous shape for cutting into a gem, it must lose half, or perhaps two-thirds, of its present weight during the process. It should then weigh 1516 carats to 1010 carats.

If, on the other hand, it has imperfections, such as internal spots, marks or flaws, it most probably will have to be divided into several or more separate stones in order to remove the faulty material.

With regard to the color, this can only be judged by the keen eye of the expert, who will compare it with other diamonds of importance, noting its resemblance to or difference from gems of standard quality.

The immense size of this diamond would certainly impress one that, if made into one gem, weighing, as already stated, 1516 carats, which is equal to 10.033 ounces troy, it not only will be with difficulty marketable, but essentially unsuitable for use as a jewel, for the size of the finished gem would be about the size of a teacup.

In addition, it must of necessity be mounted somewhat substantially for the purpose of jewelry, which would increase the weight and size of the "jewel" to still greater enormous proportions.

It will be interesting to watch the career of this great stone. Will it entirely lose its identity by

being formed into many gems, or will it ever appear upon the market as one huge brilliant of enormous price?

Until the discovery of the large stone at the Premier mine, the largest known diamond was the Excelsior, found at Jagersfontein in 1893. It weighed in the rough state 970 carats. It has been cut into no less than nine brilliants.

For the sake of further comparison, the following is a list of the greatest diamonds known, together with the weights. It must be borne in mind that these stones were cut at a very early period from the rough, so that the weights quoted are those of the stones after cutting. The original weights can only be a matter of conjecture, as the work of cutting was performed at such a remote date:

Names of Stone.	Present Weight.	Probable Original Weight.
Kohinoor.....	186 carats (reduced to 106 carats)	393 carats
Pitt (or Regent).....	137½ carats	410 carats
Great Mogul.....	279 carats	560 carats
Orloff.....	193 carats	400 carats

As far back as it is possible to obtain any records, diamonds were cut and polished in a crude way in India, and to this day may be seen in the regalias of native princes, etc., gems of untold value, the beauty of which is entirely marred by want of scientific cutting.

The earliest reference to be found of diamond cutting in modern Europe is in 1456. At this time, when Bruges was not only one of the principal ports of Europe, but an artistic center of all kinds of arts and crafts, there lived in this town a Frenchman named Louis De Burquheim, to whom is attributed the credit of first cutting diamonds with a regular arrangement of facets. De Burquheim discovered that by a certain relationship of the facets on a diamond the reflection and refraction of light were greatly increased, and, with the exception of various slight modifications, his method of polishing diamonds is adhered to to this day. Many very fine gems undoubtedly passed through De Burquheim's hands, and his name became famous in connection with his work. The industry of diamond cutting, therefore, became established and flourished at Bruges for many years, for we find a guild of diamond cutters there in 1470; but after the death of De Burquheim it eventually got dispersed to other cities, to which his pupils separated. Amsterdam, Antwerp and Paris all had their diamond cutting establishments, those of Paris being, however, the most important.

The French retained a great share of the trade, which was patronized by the wealthy and extravagant classes, and in which it is said Cardinal Mazarin took a great interest, until the troubled times of the eighteenth century. In Holland and Belgium, however, the industry of diamond cutting took so firm a root that to this day it is the principal business of Antwerp and Amsterdam.

Many fine gems are, however, cut in London, and since the placing of rough stones on the free list by the Dingley law a share of the business has been attracted to the United States, although the craftsmen employed are nearly all foreigners.

The method of cutting diamonds differs in many respects from that used in connection with all other precious stones, and, in fact, diamond polishing constitutes a distinct craft which forms the basis of an entire industry, irrespective of other precious stones. The process consists of three distinct operations—"bruting," "polishing" and "cleaving."

The "bruting" of diamonds consists of rubbing two diamonds together in such a way that by continual friction each can be made to assume the desired shape. Each diamond is cemented upon one end of a stick or holder about 1 foot long, and the operator firmly holds one of these sticks in either hand. The stones are then rubbed and pressed one against another over a wooden trough containing a very fine metal sieve, into which fall the particles of diamond dust rubbed from the stones. In order to obtain sufficient leverage, the holders upon which the diamonds are secured are held against little metal projections in either side of the trough.

The dust which falls through the metal sieve is carefully preserved and used in other parts of the process for polishing purposes. The dust is known as "diamond powder," and it has exactly the same appearance as slate pencil dust. Upon the principle of "diamond cut diamond," the stones are fashioned into the required shape, and it is the duty of the bruter to roughly fashion the stones into whatever symmetrical form he has designed them to be when finished. The small polished flats, known as facets, with which the surface of a diamond is covered are added subsequently to this, and form another part of the process.

When the bruter has completed his part of the work, the diamonds are handed to an attendant, who is seated at a bench in front of two flaring argand burners. Small brass basins, known as "dops," which vary in size from 1 to 3 inches in diameter, are placed in the flames, and each dop is filled with a mixture of tin and lead in the proportion of one part of tin to two of lead. When this metal has assumed a semi-molten state, it is fashioned into the shape of a cone by means of a large pair of soft iron tongs, and upon the apex of each cone one of the bruted diamonds is carefully embedded.

After the diamond has been carefully adjusted, the

dop containing the cone of hot metal surmounted by the diamond is plunged into cold water. The stone is then firmly fixed, the dop forming a kind of holder for it.

The stone is now ready to be handed to the polisher, but it is necessary for it to be returned from time to time to be unsoldered and readjusted, in order that a different part of the stone may be brought into prominence, as it is only possible to work upon that part of the stone which projects from the metal. This operation is repeated continually until the process of polishing is completed. The operation of embedding diamonds in the metal as I have described is known as "soldering."

The polishing of diamonds is an arduous and at the same time a delicate process. The craftsmen are seated, generally with their backs to the light, in front of revolving wheels, which are made of very porous cast iron. The wheels turn in a horizontal position at about 2500 revolutions a minute. The technical name for a diamond polishing wheel is "skeif." The dops containing the diamonds are held by means of iron clamps against the surface of the skeif, and kept in position by means of heavy weights. Four of these clamps are manipulated by each operator at the same time, and he is able to examine, first one diamond and then another, occasionally plunging each into cold water to prevent the heat generated by the friction from unsoldering the stone, which would occasion considerable damage to the gem and loss of valuable time and labor.

The surface of the skeif derives its erosive property from the continual application of diamond dust mixed with olive oil, and to the dust which comes off the stones undergoing the process. The facets are polished on to the diamonds by means of pressure against this erosive surface while it revolves at a high speed.

The diamond dust is prepared by means of steel pestles and mortars, into which fragments of bort, or coarse, valueless diamonds, are placed. By means of blows and great pressure upon the pestles the desired fineness of diamond dust is obtained.

As the diamond dops are frequently too hot to hand from one man to another with comfort, even after having been plunged into cold water as already described, wooden holders are used for the purpose of handling them more readily.

The "brilliant" is the usual form into which diamonds of any importance are cut. The front of a "brilliant" consists of an octagonal facet in the center, termed the "table," which is surrounded by thirty-two smaller facets extending from the table to what is known as the "girdle," or edge of the stone. The back of the "brilliant" is in the shape of a pyramid. The small facet at the extreme apex is known as the "collet," and there are twenty-four facets, reaching from the "collet" to the "girdle." The brilliancy of a brilliant cut diamond is due to the refraction and reflection of light from facet to facet within the gem, and a well-cut "brilliant" should be so proportioned that a ray of light entering the stone from the front is refracted about within the stone and out again from the front, thus causing the maximum of refraction.

The "rose" is another form of cutting, which is, however, only used for small, thin stones which are unsuitable for making "brilliant." The front of it is covered with six or more triangular facets of equal size, and the back is quite flat. The effect obtainable from a "rose" cut diamond is very small compared with that of a "brilliant." As the rose is devoid of the pyramid which causes the luster of a brilliant cut stone, it necessarily refracts the light in a very small degree.

The "briquette" is a pear-shaped diamond, and is covered all over with triangular facets like the front of a rose. It has neither "table," "girdle" or "collet," and is generally drilled across the narrow end in order that it may be worn swinging as a pendant or some other similar device.

Besides the three principal forms of cutting, which I have already described, diamonds are sometimes cut into what is known as "single cut" stones—that is, brilliants without the full complements of facets. It is unnecessary, however, to say that diamonds cut in this way lack in brilliancy. Thin cleavage, or slice-like pieces of diamond, are sometimes polished with one very large facet on either side surrounded, perhaps, with a few very small ones at the edge. Diamonds cut in this way are used to put in front of tiny miniatures, in which way they are mounted into rings and other jewels.

I have now to describe the process of cleaving diamonds. When it is necessary to divide a rough diamond into halves, or to remove a small projecting part of a large stone, advantage is taken of the property of cleavage—that is, the natural tendency of a diamond to divide along certain planes parallel to the faces of the octahedron. With this object in view, the diamond to be cleaved is cemented upon the end of a wooden stick or holder in such a position that the plane of cleavage to be used in the operation lies parallel to the length of the stick. The stick is firmly fixed in the center of a weight projecting from the wooden bench in front of the operator. A steel blade is held against the diamond in the desired position, and by means of a smart blow upon the back of it the stone is caused to divide along the cleavage plane.

\* Leopold Claremont in the London Min. Journal.

## Mine Superintending.

Written for the MINING AND SCIENTIFIC PRESS by  
E. RAMMELMEYER.

Much has been written about mine managing and mine superintending. This is a widely diffused field and large mines are fortunate enough to enable them to employ mine manager, mine superintendent, foreman, shift boss, assayers, surveyors, time keepers, accountants and other high-grade help. Other mines, or a large number of them, are not so fortunate as to have all these men, and I will speak here only of the mine superintendent who has charge of a mine without a large staff or who has sometimes only to rely upon his knowledge of the different departments. I do not refer at all to the manager who directs the clerical staff, keeps in touch with the owners or directors of the property or company, or who compiles the daily, weekly or monthly financial reports.

I shall dwell here only upon the duties and responsibilities of the superintendent or man in charge who has to direct and execute the work in and about a mine. His duties are multiform and his experience must be of some years standing to enable him to get a thorough insight of his detail work and to give orders understandingly.

He must be many-sided, his mental and physical energy must be tried and tested and he must be controlled and regulated by a sound mind. The experience he has gained in former years in the different departments which he has now to oversee are the prime factors for a successful mine superintendent.

First of all he must know what a day's work consists of, and they are quite different as to mining, mucking, blacksmithing, timbering, engineering, etc., and again these may be varied in different localities under different conditions. Unfamiliarity with these facts, or some of them, in a good many cases is the cause of expensive mining ventures and is disastrous to the success of properties which should yield fair returns if properly worked.

The first care of a mine superintendent when entering upon his duties in a mine will be to see that his men are safe. On entering a mine either by shaft or tunnel the proper adjustment of timbers will first attract his attention. The same vigilance has to be exercised in stopes, raises and winzes. It is often the case that by the negligence of proper timbering ore bodies cannot be extracted and miners have frequently lost their lives.

We often notice in some mines after a change of superintendents either accidents increase or vice versa. It is not always the case that these fatalities are the result of the ignorance and carelessness of the workmen. Defective hoists, skips, cages, roadways, powder thaws too close to where the men are working, and similar other instances, not here mentioned, are often wholly overlooked by the superintendent. This with a knowledge of assaying and mine surveying constitute the main factors which have to be thoroughly understood by the superintendent. But these pertain only to what he has to know to have his mine in working order underground.

Then as to the extraction of the ore. He has to consider the cost of either hand or machine work and to estimate correctly the right number of men to extract a certain amount of ore with as little expense as possible under the prevailing conditions and to improve upon them daily either by not handling the ore or waste too many times or by other contrivances as he may deem expedient. Instances occurred and came under the observation of the writer when after an expensive compressor plant was installed hand drilling had to be resorted to, it being cheaper on account of the ordinary small sized vein, thus delivering the ore clean without any waste.

To see heaps of iron, steel, broken pieces of machinery, drills, boilers, tubes, pipe, etc., lying about a mine—"no more good"—all expensive when new and now all in the waste heap, speaks volumes to a new superintendent when taking charge of a mine, and if he can read the signs he can make improvements right and left by looking through the mine and over the machinery. He must keep his eye on these parts, even the waste heap has taught him that.

He may have a hoist, boilers, water pumps, a small machine shop, blacksmith shops with engineers, blacksmiths, etc. Can he give them orders intelligently when something is broken or out of order without understanding what orders to give? Some say that he is willing to pay for the knowledge of others in the different departments under him, and which he sometimes does very dearly. His experience in different mines with pumps, hoists and other machinery, together with the up-to-date articles which treat upon these themes in the splendid mining journals of the present day, should give him such insight that he should know the workings of these machines as well as the engineers.

He must also know the geology and formation of the casings of the vein and have a knowledge of the different faults as they occur. As these can be diag-

nized, they have to be thoroughly gone into and understood by a mine superintendent.

For the most experienced mine superintendent it is sometimes puzzling to be confronted with a low-grade ore, which has to be extracted where mining and machinery is expensive, where transportation to the railroad is connected with difficulties and where freight and treatment are higher than in other localities. In places like this, ore which should yield fair returns is rendered valueless by these obstacles. Other drawbacks, such as scarcity of timber, water or fuel, or of too much water in a mine, bad air and numerous others, which are characteristic of most mining camps, tax the ingenuity, ability and experience of a superintendent to its fullest extent.

These conditions do not refer to a mine superintendent where the ore is high grade, yielding a fair profit, where the conditions are nominally good; or to where the superintendent does not have to have a varied experience provided he has a good foreman. The owners or directors also may not care as long as the mine pays well; thus a good many of his shortcomings are hid and he is ignorant of the fact that by a systematic working of the mine the profits may be considerably increased.

So a superintendent has to know a good many things, but time and space is too limited to detail any part of the different departments. By working and serving an apprenticeship in these is the only way to get familiar with and understand them intelligently.

A young mining engineer from England with letters from the head office in London came to a mine superintendent in British Columbia with the expectation of becoming assistant superintendent. The superintendent sent him to the foreman, who directed him to go to work as a mucker, whereupon the young man remonstrated, not having done that work before. The superintendent told him he began as a mucker and had not mastered it yet. Thus it may seem that a mine superintendent has to be a jack of all trades and master of none, but I may say there are a good many superintendents who have worked in all branches of their respective departments and who can fill almost any of the places creditably. I yet look back twenty-five years and more when mine superintendents moved mills and machinery from Utah 500 miles into Montana on ox teams. At their destination there were no machine shops to run to, the cost of living and labor was expensive, they had nothing to rely upon except their ingenuity to grapple with obstacles they were confronted with in new, untried districts where were their prospective mines and they were ultimately crowned with success. Skilled miners and mechanics were at a premium and not as plentiful as to-day. There the superintendent had to explain everything in, out of and about the mine to his subordinates to make a success of the undertaking.

These men are found in almost every mining camp in the Western States and territories and are much in evidence to-day, having charge of mines throughout the mining world. They have brought the present mining industry to the high standard it enjoys to-day, recognized in the financial world as the greatest factor to any industry and second to none.

It does not matter whether a mine superintendent is a graduate of a school of mines or has worked up from the bottom of the ladder, but he must understand these essentials herein stated and be a judge of human nature. These are nowadays the requirements for a successful mine superintendent.

## The Center Star Mine, Rossland, B. C.

NUMBER III—CONCLUDED.

Written by L. H. COLE.

**LOCATION OF SQUARE SETS.**—Transit set up at station 5 (see diagram); vernier at 0°, B; sight taken at station 6 and the angle turned in a clock-like direction to station 19 is measured; elevation of transit below station 5 is measured; vertical circle set at 0° and button set on line of plumb bob at station 19; horizontal distance between stations 5 and 19 measured. Transit is then set up at station 19 and angle turned to station 20, with station 5 as back sight. Station 20 is placed in the cap of the square set, the same distance from the post as station 19. Bearing of line 19-20 is then the bearing of square sets.

Stopes not having square sets are surveyed in exactly the same way as the drifts, except that a longer contour rod is used. Where the walls are very irregular, sights are taken on different points by the transit, and angle turned is read and the distance measured. The transit telescope is never plunged.

For diamond drill holes a sub-station is located on the end of the drill rod in the same way as a station is. The transit is then set up over sub-station and sight taken to collar of hole, with the last station as back sight. The line from sub-station to collar is the bearing.

The survey of stopes for the vertical projection is, in the case of narrow stopes, taken up with the transit. Transit is set up in a position (located from the nearest station) so that the back can all be seen

and sights taken to points on the back and vertical angle read and distance measured.

Square set stopes are taken up with a 14-foot rod and steel tape, since back can always be reached from the last floor.

The bearings of all lines taken underground are worked out from the azimuth of the back sight; the co-ordinates of the stations only are worked out by the traverse tables. All other points are plotted from their bearing and distances.

The working maps on which all underground work is plotted are drawn to convenient scales.

Geological maps are kept of each level, also assay sheets on which are plotted all assays run. Tracings of all maps are made for blue printing.

**SAMPLING.**—When ore is loaded on cars it is sold to the smelters, so that all sampling of shipments is made at the smelter sampling mill.

Chip samples are taken from the face and all headings, after each blast, except where running through known country, when only occasional samples are taken.

**ASSAYING.**—The samples to be assayed consist principally of diamond drill cores, daily chip samples and smelter controls. A double check is kept by assaying a floor sample as well as the ordinary control for each shipment lot. This floor sample is obtained as follows: When the last cut is made on the sampling floor of the smelter sampling mill, half is sent to the smelter assay office and the other half, which is called the floor sample at the mine, is sent directly to the mine and is treated there exactly as the other half at the smelter office. The smelter sample is ground and passed through a 120 mesh and divided into three parts. One part is assayed by the smelter, another part is the control that goes to the mine, and the third is kept for umpire. What remains on the sieve in the form of scales is cupelled separately and the result added to the pulp assay as metallics. The mine control has had these metallics extracted from it, and in order to keep a check on these metallics the above-mentioned floor sample is taken.

The control samples are assayed for gold, silver and copper. The six fusions of one-half assay ton each are run for gold and the average taken. The flux used is a litharge flux as follows:

Litharge.....	70 grams
Soda bi-carbonate.....	15 grams

and enough niter or argol to give a 20-gram button. In order to determine the quantity of niter or argol to be added, it is necessary to run a preliminary assay. The smelter uses a niter and nails flux, but the mine finds that by using a different flux it can obtain closer results. The iodide method is used for control coppers, but for all others the cyanide method is employed.

A very complete water system is now in operation, which supplies both the Center Star and War Eagle mines with water for boilers and compressors, and also for fire protection. The water comes from Center Star gulch and is handled by two high duty Cameron pumps and a duplex pump. The water is raised 500 feet through a 3-inch pipe, 2000 feet long, and discharged into a 30,000-gallon tank near the War Eagle shaft house. One hundred feet below this there is another 30,000-gallon tank, and on the slope of the hill, above the Center Star shaft house, there is another tank of the same capacity. This is provided with a 1000-gallon per minute duplex fire pump, which is always ready for immediate use (using either steam or air), and will give a pressure of 130 pounds. At the level of the company's offices a natural pressure of 160 pounds at the hydrants is obtained. The system has twenty-eight hydrants placed at convenient points to protect all the buildings of both mines.

Every employe of the company is put through a fire drill and there is a regular fire department in connection with the mine, apart from the city brigade.

Two shifts only of eight hours each are worked. The morning shift goes on at 7 A. M. and works, with an hour's intermission, until 4 P. M. The second or afternoon shift starts at 4 P. M. and with an hour for supper at 6 P. M. works till 1 A. M. Two men during the hours from 1 to 7 A. M. blast all the ground drilled and ready for breaking and turn on the blowers, thus leaving the mine free from smoke and ready for the morning shift. The scale of wages is as follows:

Shaft men.....	\$1 00*
Machine men.....	3 50
Timber men.....	3 50
Muckers.....	2 50
Carpenters.....	3 50
Machinists.....	4 00
Blacksmiths.....	4 00
Blacksmiths' helpers.....	3 00
Hoisting engineers.....	4 00
Powder and tool boys.....	2 50
Surface laborers.....	2 50

The surface men work ten-hour shifts, with the exception of the carpenters, who only work nine hours, and hoisting engineers, who work eight hours.

The contract system is used largely in both the development work and in the stoping, and is found to be very satisfactory. The miners are paid for the amount of advance made in the former and the length of holes drilled in stoping. By this means it is found that the drills are used to better advantage during the eight hour shifts.

\*Abstract Trans. Canadian Soc. Civil Engrs.

# MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

## ALASKA.

In his annual report Governor John Brady says of the mining industry in part as follows: Somewhat of the lethargy of a political year has manifested itself in the mining industry in Alaska. Excellent properties which need enlargement and reorganization were not noticed when offered for sale in Eastern markets. Claims which are partially developed and yet prospect well received but small recognition from investors. This has been rather the prevailing tone. However, in the Berner's Bay region enough has been ascertained to encourage the whole industry, for large bodies of good paying ore have been developed, the total value of which can be accurately calculated, and it runs into millions. The blocking out of large ore bodies on these claims is being vigorously pushed, and will be carried on for some time before the proper reduction works shall be constructed. The claims more immediately north of Juneau, and those in Silver Bow basin, promise better things as development work advances.

The Rodman Bay mining properties, on the north end of Baranof island, have been thrown into the hands of receivers. The claims were discovered some years ago and a company organized. A 5-stamp mill was erected for prospecting, a wharf built and a railroad 7 miles in length—almost all on trestles, sawmill, warehouse, store and other houses erected. A fine mill, with a capacity for 120 stamps, was erected, and 60 stamps were set up. Now, after a possible outlay of \$750,000, and at the moment when the work should be turning out bullion, they are in custody of the court. Mistakes in purchases of machinery, in transportation, and in construction may be made and tolerated, but if in this instance the trouble is as to the extent and value of the ore body the men who bear the responsibility should not be excused nor pardoned; they should be blacklisted and avoided by the mining community, as such methods result in incalculable harm to Alaska's mining interests. Many hopeful enterprises are just under way and need much more capital to put them on a producing and profitable basis. A great enterprise which has cost hundreds of thousands of dollars without producing a cent in return, and suddenly thrown into a receiver's hands to wind it up, makes it laborious for promoters who have propositions of good value to get any attention whatever. Alaska has suffered greatly in this way in years past. It is to be hoped that the clubs of mine owners and mine operators, which are organizing at Juneau and other centers, will see to it that any man who has been identified with a reprehensible scheme shall be debarred, and that the capital which has been solicited and obtained for opening and developing mines shall be legitimately and conscientiously employed.

Alaska's mining laws are retarding the development of some of the best properties. In Nome it is almost impossible to buy land without a cloud on the title and even two or three titles to the same piece of property do not insure absolute ownership. The appointment of new Federal judges does not help the situation as they are only the exponents of the laws, and can do nothing to better them. At present only one mining district in Alaska is not affected by the laws, because the people of the district have taken the law into their own hands and made rules and regulations governing the purchasing, location and owning of claims. This district is the Fairbanks, near the Yukon river. There has been a big rush during the past year.

In the vicinity of Ketchikan, Manager Doly of the Unik River Mining Co., when he returns from Seattle, will have men to develop the property.

Irving, Brice & Miller are working their mine on Gravina island. The ore will be run through their own mill on the property. They are putting up a new head frame.

The Cracker Jack group has twelve men employed. The Nihlack copper mine is working thirty men. They are putting in a shaft to the beach so that the ore can be loaded on to the large boats and shipped to the smelter.

O. Grissek, at Karta bay, is driving an adit tunnel of 400 feet on the ledge.

The Mansfield G. M. Co., owners of quartz and placer claims at McGinnis creek, will continue work under Superintendent Jarrett. The company's headquarters are at Mansfield, O. They will install a tram system to handle the large boulders in the placer pits. The flume carrying a 600-foot head of water to the placers was finished last fall and has not been interfered with by the winter snow. The flume is 4x6 feet and a mile in length.

## ARIZONA.

### Cochise County.

The Copper Queen and Calumet mines are shipping 2500 tons of ore daily to the smelters at Douglas.

It is locally reported that the Phelps-Dodge interests will build a railroad from southern Arizona to the coal and coke fields of Durango, Colo.

The mill and millsites, together with four mining claims in the Turquoise mining district, and belonging to the San Remo M. Co., have been sold at sheriff's sale to M. Costello for \$30,050.

### Cocconino County.

Manager S. J. Holsinger of the Standard Iron Co.'s properties at Meteor mountain has been drilling in the bottom of the crater; recently the drill struck something that it could not penetrate and the supposition is that it is a fragment of the meteor. The drill was at the depth of 630 feet; the hole had to be abandoned and a new one started, which is now down several hundred feet. The formation is a soft sandstone saturated with

water; the only trouble in drilling is to keep the sand from coming in before the piping can be put down.

### Mohave County.

The Santa Fe has absorbed the Arizona & Northern railroad, which runs from Kingman to Chloride, a distance of 35 miles.

The Andrews-Doran Co., of Los Angeles, are promoting a smelter proposition at Kingman. They have land near McConico, 4 miles south of Kingman, and say they will there install a plant of 500 tons capacity. The process is a new one and is controlled by the G. H. Reduction Co., of which Andrews & Doran are the representatives.

Kingman reports that the Gold Bug Mining Co. has bonded its group of mines to H. J. Marmein of New York for \$150,000, and that Butler & Osborne have sold their group of copper-gold mines on Big Williams Fork for \$80,000.

Operations are to be resumed at the Golden Gem, in the Cerbat range. The Golden Gem Co. will erect a concentrating plant.

### Yavapai County.

(Special Correspondence).—The Storm Cloud mines on Mount Union, 15 miles southeast of Prescott, are to be unwatered and examined preparatory to placing hoisting machinery on the property. The Storm Cloud has an inclined shaft on the vein 200 feet deep, and on the Ten Spot a vertical shaft 100 feet deep, between two veins. Besides these developments there are numerous tunnels, small shafts and surface cuts on a number of veins. The property comprises 208 acres of mineral land near the summit of Mount Union and joins the Cash Co.'s mines, and is about 1 mile from the Senator mine. The ore in the Storm Cloud is quartz, carrying gold and auriferous iron sulphide. On the Ten Spot the ore is a mixture of copper, iron, lead and zinc sulphides in quartz gangue. This mine has produced upward of \$100,000 by primitive methods. T. C. Archer of Prescott has been making arrangements for the prospective owners.

Prescott, Feb. 28.

A. J. Pickrell of Prescott is at the Senator mine, where he has men cleaning out the long tunnel, preparatory to the installation of air drills.

A new company, it is reported, has been formed to rebuild the Val Verde smelter at Val Verde. The first work will be the construction of a sampling works. The company will not wait for the completion of the smelter, but will commence to buy ore as soon as the sampling works is in operation. The system of smelting will be different from that practiced here heretofore. The new plant will be constructed upon the lines of the new smelter at El Paso, Tex., and the plant at Agua Caliente, but will have the advantages of improvements introduced during the past two years. The company expects to have the smelter in operation in from four to six months. The capacity of the smelter will be from 300 to 500 tons per day, with provision made to increase the capacity to 1000 tons a day as soon as the ore output will justify it.

The Anderson Metals Extraction Co. has started work on a cyanide plant at McCabe, to work the large pile of tailings accumulated during the past three years. There are about 25,000 tons of tailings, averaging from \$3 to \$5 per ton in gold, and between 1% and 2% copper. The plant is expected to be in operation by May 15. The company has leased the tailings. It is claimed that by the Anderson process the copper will be precipitated and also saved.

### Yuma County.

H. J. Beemer of the Amalgamated G. M. Co. at Quartzsite has spent the past two weeks at the mines supervising operations and reports work progressing. He says they do not calculate getting the 60-stamp mill in operation before July. Beemer will put a traction train on the road. A load on a good road is fifteen tons to the car. Machinery for drilling water has arrived at Congress Junction and is being hauled 100 miles to camp. The plant consists of a boiler, engine, a 58-foot derrick and complete drilling outfit. Beemer expects by July to have a complete 60-stamp mill and concentrating plant in full operation.

## ARKANSAS.

### Baxter County.

(Special Correspondence).—Several new zinc mines have lately been developed in this county, among them the Gold Standard, which is now erecting a mill, and the Commercial mine, which is placing machinery on the ground preparatory to building a mill. Three other mines will probably have mills before summer—the Hawkeye, Mountain Pass and Huelsenbeck. Scores of prospects are being developed in the vicinity of Mountain Home which will eventually become mines.—A rich strike of zinc ore is reported from the Mountain Pass claim, 3 miles west of Mountain Home.—P. H. Gehr of Mountain Home has made a zinc strike in the Yellville district.

Mountain Home, Feb. 28.

### Marion County.

(Special Correspondence).—An elevated tramway 1 mile long is being built at the Maumee mine, in the Yellville district.—The Excelsior claim, near St. Joe, is being drilled to find the boundaries of the zinc deposit developed in this locality.—The Jimmies Creek district will ship concentrates to the smelters via the new railroad at Yellville.—Superintendent Augustine of the Davy Crockett mine, near St. Joe, made his first carload shipment of zinc last week.—The Monkey Hill mine at Yellville is opening up. The gangue runs about 40% metallic zinc and the ore assays 64%.

Yellville, Feb. 28.

## CALIFORNIA.

### Amador County.

The Jose Gulch mine at Butte City, 4 miles southeast of Jackson, has been idle for several weeks. W. E. Stewart has the management of it and has succeeded in getting the title in proper shape and mine and mill will resume operations. A run of the mill was made last month which is said to have more than paid expenses.

Superintendent Weh Smith reports the 100 stamps now dropping in the Kennedy mill. The station at the

2700-foot level is about completed, the water tank finished and preparations are being made to crosscut to the ledge on that level. The total depth of the shaft is 2810 feet, and as soon as crosscutting is begun at the 2700 level sinking will be resumed and another station cut at the 2850 level.

### Butte County.

The Mercury says that H. H. Yard and W. P. Hammon are interested in the North California M. Co., which has a large tract in Butte and Plumas counties on the North and Middle Forks of Feather river. It is proposed to dig the auriferous gravels at various points with steam shovels, load it on cars and haul it from 1 to 7 miles where it may be sluiced. Where there is available water pressure, it is proposed to wash the gravel from the cars into the sluices. The cost is estimated at 5 cents per cubic yard for digging, 1 cent per mile per cubic yard for hauling and 2 cents for unloading and washing. As the company has water power for generating electricity, the use of electrical power will lessen this cost.

### Calaveras County.

F. O. Cortmarsh of Mokelumne Hill has secured the Sport Hill mine from the owner, G. Emerson, and has formed a company of local men. This property lies below the Mokelumne Hill canal and will be worked by ground sluicing.

The Bourbon Electrical & Mining Co. is preparing to install its electrical plant on the Stanislaus river. J. Fozard, formerly of the Utica Co.'s plant, above Murphys, will put in the plant on the river for the new company. He will draft his own plans.

The Melones Con. M. Co. has a tunnel into Carson hill 5300 feet. Through an 1100-foot shaft ore from the upper levels is let down to the tunnel level, where it is loaded upon trolley cars for the mill. It takes 300 tons of ore a day to keep the sixty stamps dropping. After the addition of forty more stamps, the mill's capacity will be 500 tons daily.

The lode lying west of Altaville promises to develop several paying mines, says the Echo. Recent discoveries on the lode have proved encouraging. Some of the ore taken out of late assays well in free gold. A good part of the lode is under bond.

Work is going on on the Jones-Allison group of mines on Carson creek, 6 miles southwest of Angels. Good prospects have been found in the large ledge recently discovered there.

The Cassinelli drift mine, on Central hill, 4 miles west of San Andreas, is a good producer. A clean-up last week yielded \$1000 in gold.

A number of good gravel finds have lately been made in the gravel mines about San Andreas in a district many supposed to have been worked out years ago.

### El Dorado County.

The Oakland Development Co. has started hydraulicking on the Mameluke Hill gravel mine, 1 mile north of Georgetown. M. W. Sargent is superintendent.

### Inyo County.

(Special Correspondence).—Mines near Lone Pine are being opened by J. J. Sweeney of Colorado, who is at Lone Pine. He is the promoter of the new town of Mayette, near his property. Mount Whitney station is the nearest railroad point.

Lone Pine, Feb. 28.

### Kern County.

Superintendent Galbraith of the Yellow Aster mine, near Randsburg, says he will develop the mine's water supply to increase the capacity of its mills. At present the wells of the company supply water to run 130 stamps. The present capacity is 500 tons a day. The compressed air plant runs four machine drills.

The Sunshine mine, located in 1896 by B. M. and T. W. Atkinson, 2 miles southwest of Randsburg, has recently developed ore assaying \$100 per ton. Since striking the deposit at a depth of 100 feet, ore has been mined in large quantities to the present depth, 275 feet, which is milling \$108 a ton.

### Nevada County.

Manager Brunner, of the Conlin mine, is expected at Grass Valley, to resume operations. The pumps have been kept going and the mine is free of water. The shaft is down 700 feet.

### San Bernardino County.

It is locally reported that the smelter plant at Needles will be taken hold of by a company of experienced men.

### San Diego County.
